Ad Hoc Broadcast, Trace, and Revoke
Plus Time-Space Trade-Offs for Attribute-Based Encryption

Ji Luo

University of Washington, Seattle, USA

Abstract. Traitor tracing schemes [Chor–Fiat–Naor, Crypto ’94] help content distributors fight against piracy and are defined with the content distributor as a trusted authority having access to the secret keys of all users. While the traditional model caters well to its original motivation, its centralized nature makes it unsuitable for many scenarios. For usage among mutually untrusted parties, a notion of ad hoc traitor tracing (naturally with the capability of broadcast and revocation) is proposed and studied in this work. Such a scheme allows users in the system to generate their own public/secret key pairs, without trusting any other entity. To encrypt, a list of public keys is used to identify the set of recipients, and decryption is possible with a secret key for any of the public keys in the list. In addition, there is a tracing algorithm that given a list of recipients’ public keys and a pirate decoder capable of decrypting ciphertexts encrypted to them, identifies at least one recipient whose secret key must have been used to construct the said decoder.

Two constructions are presented. The first is based on functional encryption for circuits (conceptually, obfuscation) and has constant-size ciphertext, yet its decryption time is linear in the number of recipients. The second is a generic transformation that reduces decryption time at the cost of increased ciphertext size. A matching lower bound on the trade-off between ciphertext size and decryption time is shown, indicating that the two constructions achieve all possible optimal trade-offs, i.e., they fully demonstrate the Pareto front of efficiency. The lower bound also applies to broadcast encryption (hence all mildly expressive attribute-based encryption schemes) and is of independent interest.

Keywords: ad hoc · decentralized · distributed · flexible · traitor tracing · broadcast encryption · attribute-based encryption · functional encryption · obfuscation

1 Introduction

Traitor tracing schemes [CFN94] enable content distributors to fight against piracy. A content distributor such as a media streaming service can generate a public key and many different secret keys for individual subscribers, all of which can decrypt the ciphertexts created using the public key. Given a pirate decoder capable of decrypting, which could have been created from the secret keys of multiple subscribers, the tracing algorithm can find at least one subscriber (a traitor) whose key was used to create the said decoder. A long line of subsequent works [BSW06,BW06,BN08,BZ14,NWZ16,GKW18,GKRW18,CVW’18,GQWW19,GKW19,Zha20a,Zha21,GLW23] proposed the different security definitions, extended the functionality, and presented new constructions.

While the traditional model caters well to the needs of content distributors, its centralized nature makes it unsuitable for many scenarios, e.g., when a group of individuals want to communicate among themselves and trace traitors who provide decoders to outsiders.

This research is “open-thoughts”. See https://github.com/GeeLaw/ahbtr.

For example [Zha21], in an encrypted group chat among protesters, the users are worried about potential infiltration by government agents. To mitigate this concern, they want to trace traitors and remove them from the group. If they used a traditional traitor tracing scheme, whoever set it up would be able to impersonate anyone since they would know all the secret keys. Moreover, as words are spread and the protest gets wider support, more people need to join the group. The joining process should as simple as possible, preferably without interaction. This motivation naturally calls for a decentralized notion of traitor tracing, termed ad hoc traitor tracing in this work.

The first question is thus naturally the following:

What is the right notion of a secure ad hoc traitor tracing scheme?

Having formalized its syntax and security, we study its constructions:

How can such a scheme be constructed, from what assumptions, and with what efficiency?

Efficiency improvement (in both size and time) never ends until we reach the optimum, for which it is necessary to understand where the limit stands:

What bounds are there on the efficiency of such schemes?

**Our Contributions.** We provide answers to all three questions:

- **Conceptually,** we pose the question of ad hoc traitor tracing, develop from the ideas thereof, and eventually arrive at the definitions for ad hoc broadcast, trace, and revoke (AH-BTR). We prove the relation among the security notions considered in this work.

- **Construction-wise,** we present secure AH-BTR schemes based on functional encryption for general circuits [BSW11]. With polynomial factors in the security parameter ignored, they achieve

\[
\text{encryption time } T_{\text{Enc}} = O(N),
\]

\[
\text{ciphertext size } |ct| = O(N^{1-\gamma}),
\]

\[
\text{decryption time } T_{\text{Dec}} = O(N^\gamma),
\]

for any constant \(0 \leq \gamma \leq 1\), where \(N\) is the number of recipients.

- **Questing for the ultimate efficiency,** we prove that for all secure AH-BTR,

\[
|ct| \cdot T_{\text{Dec}} = \Omega(N),
\]

so our schemes offer all possible optimal trade-offs between \(|ct|\) and \(T_{\text{Dec}}\), fully demonstrating the Pareto front of AH-BTR efficiency. Better yet, the bound holds for a restricted kind of weakly secure broadcast encryption [FN94], which is a specific case of attribute-based encryption [SW05, GPSW06]. Our result is the first space-time lower bound applicable to any computationally secure BE scheme, shedding new insights into the efficiency of ABE and BE.

A final addition is that our scheme is compatible with the existing public-key encryption schemes, i.e., the keys of such a scheme can be those of any secure public-key encryption, and there is no need to regenerate keys to take advantage of our scheme.
More on the Lower Bound. Most works on broadcast encryption have been focused on minimizing component sizes, motivating shorter ciphertexts with savings on broadcaster storage and bandwidth. Decryption time has been largely neglected. However, by our lower bound, a BE scheme with constant-size ciphertext could force each recipient to spend $\Omega(N)$ time on decryption and drive the total computational cost to $\Omega(N^2)$. In contrast, the naïve scheme encrypting to recipients individually has total cost only $O(N)$ in storage, communication, and computation.

This urges us to rethink about the goals of broadcast encryption — are short component sizes still the ultimate desideratum, given the high total cost? The lower bound, as an integral part of our results, shows that optimizing for one efficiency parameter might bring inefficiency in another, and calls the question of the trade-offs among multiple efficiency parameters of advanced forms of encryption into attention.

Open Questions. The tracing model in this work is black-box and classical, and recent works [Zha21,Zha20c] have studied white-box or quantum traitor tracing. It would be interesting to understand the ad hoc versions of those tracing models.

Another question for future investigation is whether AH-BTR can be constructed from more lightweight assumptions, such as group- or lattice-based ones, without going through obfuscation. This appears to require significant deviation from existing paradigms, as typical group-based or lattice-based constructions share public parameters among all parties so that their keys can be correlated and ciphertexts compressed, yet the motivation of AH-BTR repels any use of public parameters. See related works for more discussion on the technical challenges.

Related Works. We discuss them by aspects.

Ad Hoc, Decentralized, Distributed, or Flexible Broadcast Encryption. Decentralized BE with interactive management of recipient sets was studied in [PPS12,DPP07]. Ad hoc (also known as distributed or flexible) BE was studied in several prior/later works. Schemes based on pairing [DHMR08,WQZD10,KMW23] or witness encryption [FWW23] require global set-up, and the obfuscation-based one [BZ14] do not.

Broadcast, Trace, and Revoke. BTR [NP01,NNL01] is also known as broadcast and trace or trace and revoke. Non-AH version of BTR supporting public tracing with optimal size currently is only known from functional encryption for general circuits (polynomial hardness, same as in this work) [AKYY23,JLL23] or witness encryption or obfuscation (non-falsifiable assumptions) [NWZ16,GVW19]. BTR is also known from pairing (standard assumption) [BW06,GKSW10] with $\Theta(\sqrt{N})$-size components supporting public tracing, or from pairing (generic group model) [Zha20a] with various size trade-offs supporting secret tracing (still $\Omega(\sqrt{N})$ when size is balanced across components), or from both pairing (standard assumption) and LWE [GQWW19] with $O(N^{\epsilon})$-size ciphertexts for any constant $\epsilon > 0$ but having $\Omega(N)$-size keys and only supporting secret tracing. Regardless of public or secret traceability, these schemes generate recipients’ decryption keys correlated by the master secret key, the major downside that AH-BTR intends to address.

Continuing the discussion of technical challenges in open questions, AH-BTR implies BTR supporting public tracing with the same ciphertext size. Therefore, it makes more sense to survey the techniques for public-tracing BTR schemes, than secret-tracing or non-BTR traitor tracing ones, in search of non-obfustopia instantiations. Filtered as such, the only schemes [BW06,GKSW10] with non-trivial (i.e., sublinear) ciphertext size are pairing-based and heavily rely on shared public parameter for key correlation (enabling ciphertext compression) — antithetical to the fully decentralized nature of AH-BTR.

\footnote{While the details of the definition in each work differ, their common theme is that each recipient generates their own key pair.}
Even if we cease the insistence of having no centrally generated public parameters, the only known ad hoc type of (pairing-based) schemes are broadcast encryption [WQZD10, KMW23] without tracing, which are clever modifications of non-AH BE schemes. However, it is unclear how such adaptations can be done for [BW06,GKSW10] or, more generally, how AH-BTR can be constructed following any known pairing-based paradigms.

Registration-Based Encryption. Registered encryption [GHMR18,GHM+19,GV20,CES21, GKMR23,HLWW23,FWW23,FKdP23,FFM+23,ZZGQ23,ZLZ+24,GLWW24] is an emerging paradigm to decentralize functional encryption, where users generate their own key pairs and their public keys are aggregated for use during encryption. AH-BTR and RBE share similarities in motivation and techniques — e.g., typical constructions of both rely on laconic cryptography [CDG+17] to compress public keys.

We can conceive casting ad hoc private linear broadcast encryption, our building block of AH-BTR, as RBE for compare-index-and-reveal, yet there is no study of this functionality in the literature. Even under this view, RBE is not “ergonomic” to the usage pattern of AH-BTR and such reduction may suffer efficiency issues. The reason is that RBE requires distributing decryption updates (public information that, when used with user-generated secret keys, helps with decrypting ciphertexts encrypted using the aggregated public key) as the public keys are aggregated. RBE aggregation corresponds to the choice of recipients in AH-BTR, which happens at encryption time. Consequently, decryption updates from RBE would have to be included in every ciphertext, or every recipient must redo aggregation. Without further investigation, it is unclear whether the issue can be resolved. In this work, we study AH-BTR directly and do not try casting it under RBE.

Efficiency Parameters. Existing works studying BE [FN94,BGW05,GW09,BWZ14,AY20, AWY20,BV22,Zha20a,Wee22] and its extensions [DPP07,Del07,SF07,BZ14] have been focused on improving the sizes of various components, and the time complexity has been largely overlooked. In a rare exception, the work of [AL10] reduces the number of pairing operations during decryption down to constant, yet the overall decryption time is not among its concerns. This work brings the total decryption time into the picture.

Lower Bounds. Previous works [BC95,LS98,KYDB98,AK08,KY09,GKW15,DLY21] show a few efficiency lower bounds related to ABE and BE, yet they only apply to information-theoretically secure primitives and even specific construction techniques. Moreover, all of them prove space (ciphertext or secret key size, or their trade-off) lower bounds, whereas this work is about space-time trade-offs. Based on obfuscation [BWZ14] or both LWE and pairing [AY20], broadcast encryption with $|ct|, |sk| = O(1)$ can be achieved, circumventing all previously known bounds. A concurrent work [JLL23] proves lower bounds on (partially hiding) functional encryption, which is more expressive than BE and ABE and hence subject to stricter lower bounds than that in this work. The two works complement each other in understanding the efficiency trade-offs of advanced forms of encryption.

Organization. In Section 1.1, we provide an overview of our results. In Section 2, we present the preliminaries. In Section 3, we formally define ad hoc broadcast, trace, and revoke (AH-BTR) and its security notions, and prove the relation among them. In Section 4, we define ad hoc private linear broadcast encryption (AH-PLBE), an intermediate object for constructing AH-BTR, and construct such a scheme. In Section 5, we present the construction of AH-BTR from AH-PLBE. In Section 6, we show how to trade ciphertext size for decryption time in AH-BTR. In Section 7, we prove the lower bound of the trade-offs between ciphertext size and decryption time.

The technical parts of the preliminaries (those beyond the opening paragraphs) are only needed for the constructions. Sections 3 and 7 do not depend on them.
1.1 Overview

**Developing Definitions.** We start with the first principles of *ad hoc* traitor tracing. Syntactically, there should be a key generation algorithm that is run by each user of the system.\(^3\) To encrypt, a list of public keys is used to identify the set of recipients. Decryption should only require one secret key from the list of public keys. In addition, the decryptor gets random access to all the recipients’ public keys as well as the ciphertext. The choice to give random access to these inputs is based on performance concerns, as the decryptor might not have to read all of the public keys or the ciphertext.

It should be clear that such a scheme would automatically have the functionality of broadcast encryption [FN94]. There is no event prior to encryption that “binds” the system to a specific, fixed set of possible recipients, and the encryptor is free to use whatever public keys it sees fit. Similarly, the encryptor can remove any public key when it encrypts a second ciphertext, i.e., the scheme supports revocation. Therefore, the object is named *ad hoc* broadcast, trace, and revoke (AH-BTR).

As usual with broadcast encryption, we do not hide the list of recipients and provide the recipient list for free during decryption. Hiding the recipients makes ciphertext grow at least linearly with the number of recipients, diminishing the potential of efficiency. As we shall see, it is possible to construct AH-BTR with short ciphertexts.

Due to the decentralized nature of such systems, an adversary might indistinguishably generate malformed keys, which could potentially evade tracers that only take well-formed keys into account. To make it worse, a malformed key could be used to mount a denial-of-service attack against (other) honest users if it appears in the list of recipients’ public keys during encryption — the encryption algorithm might have been carelessly designed and the presence of certain malformed keys could make it impossible to decrypt for anyone, including the recipients with honestly generated public keys.

In order to protect against such attacks by definition, we require correctness be *robust* against malformed keys — however, for performance reasons, namely to be able to index into any particular public key in constant time, we reject *blatantly* malformed keys, e.g., those of incorrect lengths, in the definition of correctness. This restriction does not hamper the usefulness of such a scheme.

As for security, we naturally consider *public traceability*, i.e., no secret key is required to run the tracing algorithm. When attacking the scheme, the adversary is allowed to supply an arbitrary list of recipients’ public keys, generated honestly by the challenger or (adversarially) by the adversary, so that the definition covers the scenario when (blatantly or not) malformed keys are present in the list of recipients’ public keys. The tracing algorithm is given oracle access to a stateless\(^4\) decoder. It must *not accuse* an honest user, defined as one whose public key is generated by the challenger without its secret key revealed to the adversary. It *must find* a traitor as long as the decoder breaks semantic security (i.e., succeeds in decrypting with non-negligible probability), where *traitors* are associated with public keys in the recipient list that are either generated by the challenger yet having their secret keys revealed to the adversary or crafted by the adversary in any manner (e.g., skewed distribution, or even without a well-defined secret key).

The issues above must be identified and conceptually resolved (as done here) to arrive at suitable definitions accurately capturing the decentralized nature of AH-BTR.

**Simplifying Security Notions.** Traditionally [BSW06], traceability has been defined using one comprehensive *interactive* experiment,\(^5\) which is complicated to work with.

---

\(^3\)We aim for a scheme without any trusted party, so there should be no global set-up.

\(^4\)The general transformation [KY01,BSW06] to deal with stateful decoder applies to our definition of AH-BTR, *mutatis mutandis*.

\(^5\)While some previous works [BF99,GKW18,Zha20a] separate traceability into multiple notions, each notion still requires interaction in its security experiment, due to the centralized nature of the set-up process of traditional traitor tracing.
Intuitively, the notion requires that (i) a traitor should be found from a decoder with sufficient advantage and (ii) no honest user should be identified as a traitor, regardless of the decoder advantage.

We thus define two security notions for AH-BTR capturing the requirements separately. The former is called \textit{completeness} and the latter is called \textit{soundness}. Their conjunction is equivalent to \textit{traceability}. Since only one requirement is considered in each notion, both of them can be vastly simplified and the security experiments become \textit{non-interactive}. They are much more convenient for reductionist proofs.

\textbf{Construction.} Our first construction of AH-BTR adapts the blueprint of obtaining traitor tracing schemes from private linear broadcast encryption (PLBE) schemes introduced in [BSW06]. We consider \textit{ad hoc} PLBE:\footnote{AH-PLBE can be cast as multi-authority attribute-based encryption [Cha07] for 1-local monotone functions without global set-up.}

- Everyone generates their own public and secret key pair \((pk, sk)\).
- Encryption uses a list \(\{pk_j\}_{j \in [N]}\) of \(N\) public keys of the recipients as well as a cut-off index \(0 \leq i_{\perp} \leq N\).
- Decryption is possible with \(sk_j\) if (and only if) \(j > i_{\perp}\).

There are two security requirements. Message-hiding requires that the plaintext is hidden if \(i_{\perp} = N\). Index-hiding requires that an adversary without \(sk_j\) for an honest \(pk_j\) cannot distinguish between cut-off index being \((j - 1)\) versus \(j\).

Colloquially, the cut-off index \(i_{\perp}\) disables \(sk_1, \ldots, sk_{i_{\perp}}\), and the only way to detect whether an index is disabled is to have control over the corresponding key pair (by knowing \(sk\) or generating a malformed \(pk\)). When \(i_{\perp} = N\), the plaintext should be hidden since all keys are disabled.

An AH-PLBE scheme gives rise to an AH-BTR scheme. The AH-BTR inherits the key generation and decryption algorithms from AH-PLBE. To perform AH-BTR encryption, simply encrypt using AH-PLBE with \(i_{\perp} = 0\), disabling no key so that every recipient can decrypt. Given a pirate decoder with advantage at least \(\varepsilon\), the tracing algorithm estimates its advantages with the cut-off index \(i_{\perp}\) being \(0, 1, 2, \ldots, N\), and identifies the recipient associated with \(pk_{i^*}\), as a traitor if the advantage changes by \(\Omega(\varepsilon/N)\) when \(i_{\perp}\) increases from \((i^* - 1)\) to \(i^*\).

For security, the message-hiding property translates to completeness, and index-hiding to soundness. It now remains to construct an AH-PLBE.

\textit{Constructing AH-PLBE.} It is folklore that any public-key encryption (PKE) scheme can be used to construct a naïve PLBE by encrypting individually to each recipient. The individual ciphertext that corresponds to a disabled key encrypts garbage instead of the actual plaintext. This scheme is also \textit{ad hoc}. The downside of it is that the ciphertext is of size \(\Omega(N)\).

Our scheme uses obfuscation to help compressing the naïve PLBE ciphertext. The ciphertext will contain an obfuscated program, which, when evaluated at \(j \in [N]\), allows us to recover the PKE ciphertext under \(pk_j\). However, the obfuscated program itself cannot simply compute each PKE ciphertext if we want AH-PLBE ciphertexts of size \(o(N)\), as there is no enough space in the program to encode all the public keys that have been independently generated. Instead, the program encodes a short hash bound to the long list of public keys while supporting computation on them.

Laconic oblivious transfer (OT) [CDG+17] serves the purpose. It allows compressing an arbitrarily long string \(D\) down to a fixed-length hash \(h\) with which one can efficiently perform oblivious transfer. The sender can encrypt messages \(L_0, L_1\) to a hash \(h\) and an
index $m$ into $D$. The time to encrypt is independent of the length of $D$. The receiver will be able to obtain $L_{D[m]}$ by decrypting the laconic OT ciphertext.

During AH-PLBE encryption, we use laconic OT to compress the list of public keys. The obfuscated program in our AH-PLBE ciphertext, when evaluated at $j \in [N]$, will output $i) a$ garbled circuit whose input (resp. output) is a PKE public key (resp. ciphertext) and $ii) a$ bunch of laconic OT ciphertexts that decrypts to the labels so that the garbled circuit is evaluated at $pk_j$. Decryption proceeds in the obvious manner.

The obfuscated program size, thus the ciphertext size, can be made constant,\footnote{We ignore fixed polynomial factors in the security parameter. The point is that the size does not grow with $N$, the number of recipients. Furthermore, exact dependency on $\lambda$ is only meaningful for concrete security, whereas this work focuses on polynomial security, in which scenario one can arbitrarily tune down such dependency by setting $\lambda' = \lambda' x$ for any constant $x > 0$, where $\lambda'$ is the actual value of the security parameter to use for the algorithms without affecting polynomial security.} because both the time to garble a PKE encryption circuit and the time of laconic OT encryptions are constant.

YOU CAN (NOT) OPTIMIZE. While our first construction enjoys constant-size ciphertext, its decryption algorithm runs in time $\Omega(N)$. Concretely, the laconic OT hash is a Merkle tree, and before performing laconic OT decryption, it is necessary to reconstruct the tree as it is not stored in the ciphertext. In contrast, the decryption time of the scheme implied by the naïve PLBE is constant in the RAM model, as it only looks at the relevant piece of the underlying PKE ciphertext.

We can trade ciphertext size for decryption time by using the naïve PLBE on top of our basic construction over each set, we obtain a scheme with ciphertext size $\Theta(N^{1-\gamma})$ and decryption time $\Theta(N^\gamma)$. The core idea of this transformation was formalized as the user expansion compiler [Zha20a] in the context of traditional traitor tracing.

All the constructions we now know have $|ct| \cdot T_{Dec} = \Omega(N)$, where $|ct|$ is the ciphertext length and $T_{Dec}$ is the decryption time. It turns out that this bound necessarily holds for all secure AH-BTR, and the blame is on the functionality of broadcast encryption (not traitor tracing). Indeed, it is possible to make both $|ct|$ and $T_{Dec}$ constant in a traditional traitor tracing scheme [BZ14]. In existing broadcast encryption (or revocation) schemes [BGW05, Del07,GW09,BZ14,AY20,AWY20,BV22] for $N$ users, encrypting to arbitrary subsets of size $S$ or $(N - S)$ makes $|ct| \cdot T_{Dec} = \Omega(S)$. It is precisely the capability to encrypt to many $(N/2)$-subsets among $N$ users that is the deal breaker, as we shall see in the formal proof. Interestingly, the adversary used in the proof simply runs the decryption algorithm with a non-decrypting key (while lying about the recipient set), so the bound holds as long as the scheme is not blatantly insecure.

We explain the ideas of our proof based on a corollary\footnote{This corollary is also a lower bound of a probabilistic variant of Yao's box problem [Yao90] (generalized and studied in [CHK22]), on which our proof can be alternatively based.} of a result [Unr07] dealing with random oracles in the presence of non-uniform advice. Let $S, T \geq 0$ be such that $ST \ll N$. The corollary says that for any adversary learning any $S$-bit function (advice) of a random string $R \in \{0, 1\}^N$ and additionally (adaptively) querying at most $T$ bits in $R$, it is “indistinguishable” to flip a bit in $R$ at a random location after the advice is computed (using the non-flipped $R$) and before queries are answered, even if the index of the potentially flipped bit is revealed to the adversary after the advice is computed.

Back to AH-BTR. Imagine that there are $2N$ users in the system, associated with key pairs $(pk_{j,s}, sk_{j,s})$ for $j \in [N]$ and $s \in \{0, 1\}$. Consider a ciphertext $ct$ encrypting a random plaintext to $\{pk_{j,R[j]}\}_{j \in [N]}$ for a random string $R$ and regard $ct$ as the advice. Suppose $Y$ is either $R$ itself or $R$ flipped at index $i^*$ $\in [N]$. Let’s try decrypting $ct$ using $sk_{i^*, Y[j^*]}$ while pretending that $ct$ is generated for $Y$. Each time the AH-BTR decryption algorithm wants to read $pk_{j}$, we probe $Y[j]$ and respond with $pk_{j,Y[j]}$. By way of contradiction,
suppose |ct| · T_{Dec} ≪ N, which would translate to ST ≪ N in the corollary.

By the correctness of AH-BTR, when Y is R itself, the attempted decryption should successfully recover the plaintext. From the corollary it follows that the other case (Y is R flipped at i∗) should also lead to successful recovery. But if Y[i∗] = ¬R[i∗], by the security of AH-BTR, the attempted decryption must fail to recover the plaintext except for negligible probability, yielding a contradiction.

## 2 Preliminaries

We denote by λ ∈ ℤ the security parameter, by poly(·) a polynomial function, and by negl(λ) a negligible function of λ. Efficient algorithms are probabilistic random-access machines $M^w(x)$ of running time poly(|x|, |w|). Efficient adversaries (in interactive experiments) are probabilistic Turing machines of (total) running time poly(λ), with or without poly(λ)-long advices. (All of the proofs in this work are uniform.) The advantage of $A$ in distinguishing $\mathsf{Exp}_0$ and $\mathsf{Exp}_1$ is $\Pr[\mathsf{Exp}_0^A(1^n) = 1] - \Pr[\mathsf{Exp}_1^A(1^n) = 1]$. We write ≈, ≈_s, ≡ for computational indistinguishability, statistical indistinguishability, and identity.

Under the standard assumption that a pseudorandom generator (with polynomial security) exists, we can assume, whenever convenient, that a randomized algorithm uses a uniformly random λ-bit string as its randomness (without losing polynomial security considered in this work or degrading its efficiency).

For $n, n' \in \mathbb{N}$, we write $[n..n']$ for the set $\{n, \ldots, n'\}$, and $[n]$ for $\{1..n\}$. For a bit-string $D$, we denote by $|D|$ its bit-length, and given an index $m \in [|D|]$, we denote by $D[m]$ the $m^{th}$ bit of $D$. For two bit-strings $D, D'$, their concatenation is $D \| D'$. Given a circuit $C : \{0, 1\}^{n+M_0} \to \{0, 1\}^{n'}$ and $w \in \{0, 1\}^n$, we define $C[w]$ to be $C$ with $w$ hardwired as its first portion of input, so $C[w](x) = C(w \| x)$. For an event $X$, its indicator random variable is $\mathbb{1}_X$. For events $X, Y$ in the same probability space, “$X$ implies $Y$” means $X \subseteq Y$.

**Garbled Circuits.** The following version of partially hiding garbling [IW14] suffices for the purpose of this work.

**Definition 1** (garbled circuit [Yao86,LP09,BHR12,IW14]). A circuit garbling scheme consists of 2 efficient algorithms:

- **Garble**($1^λ, C, w$) takes as input a circuit $C : \{0, 1\}^{n+M_0} \to \{0, 1\}^{n'}$ and some hardwired input $w \in \{0, 1\}^n$. It outputs a garbled circuit $\hat{C}$ and $M_0$ pairs of labels $L_{m_0,b} \in \{0, 1\}^λ$ for $m_0 \in [M_0]$, $b \in \{0, 1\}$.
- **Eval**($1^λ, \hat{C}, x, \{L_{m_0}\} \forall m_0 \in [M_0]$) takes as input a garbled circuit, a non-hardwired input, and $M_0$ labels. It outputs an $n'$-bit string.

The scheme must be **correct**, i.e., for all $\lambda \in \mathbb{N}$, $n, M_0, n' \in \mathbb{N}$, $C : \{0, 1\}^{n+M_0} \to \{0, 1\}^{n'}$, $w \in \{0, 1\}^n$, $x \in \{0, 1\}^{M_0}$,

$$\Pr\left[\left(\hat{C}, \{L_{m_0,b}\} \forall m_0 \in [M_0], b \in \{0, 1\}\right) \in \mathcal{G}\text{ Garble}(1^λ, C, w) : \text{Eval}(1^λ, \hat{C}, x, \{L_{m_0}\} \forall m_0 \in [M_0]) = C[w](x)\right] = 1.$$

**Definition 2** (garbled circuit security [Yao86,LP09,BHR12,IW14]). Let (Garble, Eval) be a circuit garbling scheme (Definition 1). A simulator is an efficient algorithm

$\text{SimGarble}(1^λ, C : \{0, 1\}^{n+M_0} \to \{0, 1\}^{n'}, x \in \{0, 1\}^{M_0}, y \in \{0, 1\}^{n'}) \to (\hat{C}, \{L_{m_0}\} \forall m_0 \in [M_0])$

taking as input a circuit, a non-hardwired input, and a circuit output, and producing a simulated garbled circuit and $M_0$ simulated labels. The scheme is $w$-hiding (or secure for
the purpose of this work) if there exists a simulator SimGarble such that Exp$^0_{GC} \approx Exp^1_{GC}$, where Exp$^b_{GC}(1^\lambda)$ with adversary $A$ proceeds as follows:

- **Challenge.** Launch $A(1^\lambda)$ and receive a circuit $C : \{0,1\}^{n+M_0} \rightarrow \{0,1\}^{n'}$, a hard-wired input $w \in \{0,1\}^b$, and a non-hardwired input $x \in \{0,1\}^{M_0}$ from it. Run

  \[
  \begin{align*}
  &\text{if } b = 0, \quad (\hat{C}, \{L_{m_0,b}\}_{m_0 \in [M_0], b \in \{0,1\}}) \leftarrow \text{Garble}(1^\lambda, C, w); \\
  &\text{if } b = 1, \quad (\hat{C}, \{L_{m_0,x[m_0]}\}_{m_0 \in [M_0]}) \leftarrow \text{SimGarble}(1^\lambda, C, x, C[w](x));
  \end{align*}
\]

  and send $(\hat{C}, \{L_{m_0,x[m_0]}\}_{m_0 \in [M_0]})$ to $A$.

- **Guess.** $A$ outputs a bit $b'$, which is the output of the experiment.

**Puncturable Pseudorandom Function.** We rely on PPRF [BW13,KPTZ13,BGI14,SW14].

**Definition 3 (PPRF [BW13,KPTZ13,BGI14,SW14]).** A puncturable pseudorandom function (PPRF) family (with key space, domain, and codomain $\{0,1\}^\lambda$) consists of 2 efficient algorithms:

- **Puncture**$(1^\lambda, k \in \{0,1\}^\lambda, x)$ takes as input a non-punctured key and a point. It outputs a punctured key $\hat{k}_x$.

- **Eval**$(1^\lambda, k, x \in \{0,1\}^\lambda)$ takes as input a (punctured or non-punctured) key and a point. It is deterministic and outputs a $\lambda$-bit string.

The scheme must be correct, i.e., for all $\lambda \in \mathbb{N}$, $x, x' \in \{0,1\}^\lambda$ such that $x \neq x'$,

\[
\Pr\left[k \xleftarrow{\$} \{0,1\}^\lambda, \hat{k}_x \xleftarrow{\$} \text{Puncture}(1^\lambda, k, x) : \text{Eval}(1^\lambda, k, x') = \text{Eval}(1^\lambda, \hat{k}_x, x')\right] = 1.
\]

**Definition 4 (PPRF security [BW13,KPTZ13,BGI14,SW14]).** A PPRF (Puncture, Eval) per Definition 3 is pseudorandom at the punctured point (or secure for the purpose of this work) if Exp$^b_{PPRF} \approx Exp^1_{PPRF}$, where Exp$^b_{PPRF}(1^\lambda)$ with adversary $A$ proceeds as follows:

- **Challenge.** Launch $A(1^\lambda)$ and receive from it a point $x \in \{0,1\}^\lambda$. Run

  \[
  \begin{align*}
  &k \xleftarrow{\$} \{0,1\}^\lambda, \quad \hat{k}_x \xleftarrow{\$} \text{Puncture}(1^\lambda, k, x), \quad r_0 \leftarrow \text{Eval}(1^\lambda, k, x), \quad r_1 \xleftarrow{\$} \{0,1\}^\lambda,
  \end{align*}
\]

  and send $(\hat{k}_x, r_k)$ to $A$.

- **Guess.** $A$ outputs a bit $b'$, which is the output of the experiment.

**Public-Key Encryption.** Our ad hoc broadcast, trace, and revoke scheme can be based on any public-key encryption scheme.

**Definition 5 (PKE).** A public-key encryption (PKE) scheme (with message space $\{0,1\}^\lambda$ and public key length $M_0(\lambda)$) consists of 3 efficient algorithms:

- **Gen**$(1^\lambda)$ outputs a pair $(pk, sk)$ of public and secret keys with $|pk| = M_0(\lambda)$.

- **Enc**$(1^\lambda, pk, \mu \in \{0,1\}^\lambda)$ takes as input the public key and a message. It outputs a ciphertext $ct$.

- **Dec**$(1^\lambda, sk, ct)$ takes as input the secret key and a ciphertext. It outputs a message.
The scheme must be correct, i.e., for all $\lambda \in \mathbb{N}$, $\mu \in \{0,1\}^\lambda$,
\[
\Pr\left[(pk, sk) \xleftarrow{\$} \text{Gen}(1^\lambda) \quad \text{ct} \xleftarrow{\$} \text{Enc}(1^\lambda, pk, \mu) : \text{Dec}(1^\lambda, sk, \text{ct}) = \mu\right] = 1.
\]

**Definition 6 (PKE security).** A PKE scheme $(\text{Gen}, \text{Enc}, \text{Dec})$ per Definition 5 is semantically secure for random messages (or secure for the purpose of this work) if
\[
\{(1^\lambda, \mu_0 + \mu_1, pk, ct_0)\}_{\lambda \in \mathbb{N}} \approx \{(1^\lambda, \mu_0, \mu_1, pk, ct_1)\}_{\lambda \in \mathbb{N}},
\]
where $(pk, sk) \xleftarrow{\$} \text{Gen}(1^\lambda)$ and $\mu_b \xleftarrow{\$} \{0,1\}^\lambda$, $ct_b \xleftarrow{\$} \text{Enc}(1^\lambda, pk, \mu_b)$ for $b \in \{0,1\}$.

**Laconic Oblivious Transfer.** We rely on laconic oblivious transfer [CDG+17].

**Definition 7 (laconic OT [CDG+17]).** A laconic oblivious transfer (OT) scheme (with message space $\{0,1\}^\lambda$) consists of 4 efficient algorithms:

- **Gen**$(1^\lambda, M \in \mathbb{N})$ takes the database length as input and outputs a hash key $hk$.
- **Hash**$(1^\lambda, hk, D \in \{0,1\}^M)$ takes as input a hash key and a database. The algorithm is deterministic, runs in time $(M + 1)\text{poly}(\lambda, \log(M + 1))$, and outputs a hash $h$ of length $\text{poly}(\lambda, \log(M + 1))$ and a processed database $\hat{D}$.
- **Send**$(1^\lambda, hk, h, m \in [M], L_0 \in \{0,1\}^\lambda, L_1 \in \{0,1\}^\lambda)$ takes as input a hash key, a hash, an index, and two labels (messages). It outputs a ciphertext $ct$.
- **Recv**$(1^\lambda, hk, h, m \in [M], ct)$ is given random access to a processed database, and takes as input a hash key, a hash, an index, and a ciphertext. The algorithm runs in time $\text{poly}(\lambda, \log(M + 1))$ and outputs a label (message).

The scheme must be correct, i.e., for all $\lambda, M \in \mathbb{N}$, $D \in \{0,1\}^M$, $m \in [M]$, $L_0, L_1 \in \{0,1\}^\lambda$,
\[
\Pr\left[hk \xleftarrow{\$} \text{Gen}(1^\lambda, M), \quad (h, \hat{D}) \leftarrow \text{Hash}(1^\lambda, hk, D) \quad : \text{Recv}(1^\lambda, hk, h, m, ct) = L_{D[m]}\right] = 1.
\]

We only need database-selective security [AL18]. The following indistinguishability-based definition is equivalent to the usual simulation-based formulation.

**Definition 8 (laconic OT security [CDG+17,AL18,KNTY19]).** A laconic OT scheme $(\text{Gen}, \text{Hash}, \text{Send}, \text{Recv})$ per Definition 7 is database-selectively sender-private (or secure for the purpose of this work) if $\text{Exp}_{\text{PKE}}^{\text{LOT}} \approx \text{Exp}_{\text{PKE}}^{\text{OT}}$, where $\text{Exp}_{\text{PKE}}^{\text{LOT}}(1^\lambda)$ with adversary $\mathcal{A}$ proceeds as follows:

- **Setup.** Launch $\mathcal{A}(1^\lambda)$ and receive from it some $M \in \mathbb{N}$ and a database $D \in \{0,1\}^M$.
  Run
  
  \[
  hk \xleftarrow{\$} \text{Gen}(1^\lambda, M), \quad (h, \hat{D}) \leftarrow \text{Hash}(1^\lambda, hk, D),
  \]
  and send $hk$ to $\mathcal{A}$.
- **Challenge.** $\mathcal{A}$ submits an index $m \in [M]$ and two labels (messages) $L_0, L_1 \in \{0,1\}^\lambda$.
  Run
  
  \[
  \text{ct} \xleftarrow{\$} \begin{cases} \text{Send}(1^\lambda, hk, h, m, L_0, L_1), & \text{if } b = 0; \\ \text{Send}(1^\lambda, hk, h, m, L_{D[m]}, L_{D[m]}), & \text{if } b = 1; \end{cases}
  \]
  and send $\text{ct}$ to $\mathcal{A}$.
- **Guess.** $\mathcal{A}$ outputs a bit $b'$, which is the output of the experiment.
Obfuscation. We rely on indistinguishability obfuscator for polynomial-sized domain.

Definition 9 ((circuit) obfuscator [BGI+01]). A (circuit) obfuscator is an efficient algorithm $\text{Obf}(1^\lambda, C)$ taking a circuit $C : \{0, 1\}^n \rightarrow \{0, 1\}^{n'}$ as input and producing a circuit $\tilde{C} : \{0, 1\}^n \rightarrow \{0, 1\}^{n''}$ as output. The scheme must be correct, i.e., for all $\lambda \in \mathbb{N}$, $n, n' \in \mathbb{N}$, $C : \{0, 1\}^n \rightarrow \{0, 1\}^{n'}$, $x \in \{0, 1\}^n$,

$$\Pr[\text{Obf}(1^\lambda, C)(x) = C(x)] = 1.$$

Definition 10 ($iO$ [BGI+01] for poly($\lambda$)-sized domain). An obfuscator $\text{Obf}$ (Definition 9) is an indistinguishability obfuscator for polynomial-sized domain ($iO$ for poly($\lambda$)-sized domain) if $\text{Exp}_0^0 iO \approx \text{Exp}_1^1 iO$, where $\text{Exp}_b^i(1^\lambda)$ with adversary $A$ proceeds as follows:

- Challenge. Launch $A(1^\lambda)$ and receive from it the domain size $1^{2^n}$ and two circuits $C_0, C_1 : \{0, 1\}^n \rightarrow \{0, 1\}^{n'}$. Send $\text{Obf}(1^\lambda, C_b)$ to $A$.

- Guess. $A$ outputs a bit $b'$. The output of the experiment is $b'$ if $C_0, C_1$ have the same (description) size and $C_0(x) = C_1(x)$ for all $x \in \{0, 1\}^n$. Otherwise, the output is set to 0.

Assumption. All of the primitives defined in this section are implied by the existence of weakly selectively secure, single key, and sublinearly succinct public-key functional encryption for general circuits (so-called obfuscation-minimum PKFE), of which we refer the reader to [KNTY19] for the precise definition.

Lemma 1. Suppose there exists an obfuscation-minimum PKFE with polynomial security, then there exist

- [Yao86,LP09,BHR12] a secure circuit garbling scheme,
- [GGM84,BW13,KPTZ13,BGI14] a secure PPRF,
- [folklore] a secure PKE scheme,
- [CDG+17,LZ17,AL18,KNTY19] a secure laconic OT scheme, and
- [LT17,LZ17] an $iO$ for poly($\lambda$)-sized domain,

with polynomial security.

Alternatively, those primitives can be based on the existence of $iO$ and one-way function. However, $iO$ security (for circuits whose domains are not necessarily poly($\lambda$)-sized) is not known to be falsifiable [GW11] and it is hard to conceive [GGSW13] a reduction of $iO$ security to complexity assumptions [GK16]. Since all of the security notions defined in this section are falsifiable, it is unsatisfactory to base them on $iO$ from a theoretical point of view.

In contrast, obfuscation-minimum PKFE security is falsifiable and there are constructions [JLS21,JLS22] from well-studied complexity assumptions. The point of Lemma 1 is to base our constructions solely on one falsifiable assumption, or even complexity assumptions.

3 Ad Hoc Broadcast, Trace, and Revoke

This section concerns the definitions for ad hoc broadcast, trace, and revoke. After formally defining the syntax and correctness of AH-BTR, we present an intuitive definition of its security. While that definition is comprehensive, it is not the easiest to work with, so
we turn to define two simpler security notions, whose conjunction is equivalent to the comprehensive definition. The proof of their equivalence follows the definitions. Later in this paper, we will only work with the simpler notions.

**Definition 11** (AH-BTR). An ad hoc broadcast, trace, and revoke (AH-BTR) scheme (with message space \(\{0,1\}^\lambda\) and public key length \(M_0(\lambda)\)) consists of 4 efficient algorithms:

- **Gen**(1\(^\lambda\)) outputs a pair \((pk, sk)\) of public and secret keys with \(|pk| = M_0(\lambda)\).
- **Enc**(1\(^\lambda\), \(\{pk_j\}_{j \in [N]}, \mu \in \{0,1\}^\lambda\)) takes as input a list of public keys and a message. It outputs a ciphertext \(ct\).
- **Dec**\((pk_i, sk_i)\) is given random access to a list of public keys and a ciphertext, and takes as input the length of the list, an index, and a secret key. It outputs a message.
- **Trace**\((1^\lambda, \{pk_j\}_{j \in [N]}, 1^{1/\epsilon^*})\) is given oracle access to a (stateless randomized) distinguisher \(D\) and takes as input a list of public keys and an error bound (in unary). It outputs an index \(i^* \in \{\bot\} \cup [N]\).

The scheme must be *robustly correct*, i.e., for all \(\lambda \in \mathbb{N}, N \in \mathbb{N}, i \in [N], \{pk_j\}_{j \in [N] \setminus \{i\}}\) such that \(|pk_j| = M_0(\lambda)\) for all \(j \in [N] \setminus \{i\}\), and \(\mu \in \{0,1\}^\lambda\),

\[
\Pr \left[ (pk_i, sk_i) \xleftarrow{\$} \text{Gen}(1^\lambda), \ c_t \xleftarrow{\$} \text{Enc}(1^\lambda, \{pk_j\}_{j \in [N]}, \mu) : \text{Dec}(pk_i, sk_i) = \mu \right] = 1.
\]

**Definition 12** (traceability). An AH-BTR scheme \((\text{Gen, Enc, Dec, Trace})\) per Definition 11 is *traceable* if all efficient adversaries win \(\text{Exp}_{\text{Trace}}\) only with negligible probability, where \(\text{Exp}_{\text{Trace}}(1^\lambda)\) with adversary \(B\) proceeds as follows:

- **Setup.** Launch \(B(1^\lambda)\). Initialize the set \(S\) to \(\emptyset\) and let \(Q \leftarrow 0\).
- **Query.** Repeat the following for arbitrarily many rounds determined by \(B\). In each round, \(B\) has two options:
  - \(B\) can request that a new user be initialized and obtain the newly generated public key. Upon this request, let \(Q \leftarrow Q + 1\), run
    \[
    (pk_Q, sk_Q) \xleftarrow{\$} \text{Gen}(1^\lambda),
    \]
    insert \(Q\) into \(S\), and send \(pk_Q\) to \(B\).
  - \(B\) can query for \(sk_t\) by submitting \(t \in [Q]\). Upon this query, remove \(t\) from \(S\) and send \(sk_t\) to \(B\).
- **Challenge.** \(B\) outputs a (probabilistic) circuit \(D\), a list \(\{pk_j^*\}_{j \in [N]}\) of public keys, and an error bound \(1^{1/\epsilon^*}\) in unary. Run
  \[
  i^* \xleftarrow{\$} \text{Trace}(1^\lambda, \{pk_j^*\}_{j \in [N]}, 1^{1/\epsilon^*}).
  \]

---

9Considering an index instead of a set of indices does not lose currently provable properties. The issue with existing formalism is that there is no known way to define the “true” set of traitors (e.g., a user whose secret key is revealed to then immediately discarded by the adversary is not a “true” traitor, which should not and cannot be identified by Trace), hence the security definition cannot require Trace to catch all “true” traitors. Consequently, we can only require it to and prove that it does identify at least one traitor. Our constructions can be modified to potentially find multiple traitors in the usual way [BSW06].

10These public keys could be out of the support of Gen, i.e., malformed.
AH-BTR as defined above is a key-encapsulation mechanism, following [Zha20a]. Using with traceability under adversarially chosen messages. As noted in Remark 3 of [Zha20b], traceability implies KEM security (or IND-CPA when combined with hybrid encryption).

3.1 Simplified Security Notions

The traceability of AH-BTR guarantees that a traitor must be found (if the decoder has high advantage) and innocent users must not be accused (regardless of the advantage of the decoder). Decomposing the two requirements (plus some apparent weakening) makes each of them simpler (in particular, non-interactive) in the decentralized setting.\footnote{Similar simplification to non-interactive security experiments also works, mutatis mutandis, for the usual definitions considering a set of traitors identified by Trace.} The first requirement is called completeness, and the second soundness.

**Definition 13 (completeness).** An AH-BTR scheme \((\text{Gen}, \text{Enc}, \text{Dec}, \text{Trace})\) per Definition 11 is complete if all efficient adversaries win \(\text{Exp}_{\text{complete}}\) only with negligible probability, where \(\text{Exp}_{\text{complete}}(1^\lambda)\) with adversary \(\mathcal{C}\) proceeds as follows:

- **Challenge.** Launch \(\mathcal{C}(1^\lambda)\), which outputs a (probabilistic) circuit \(\mathcal{D}\), a list \(\{pk^*_j\}_{j \in [N]}\) of public keys, and an error bound \(1/\epsilon^*\) in unary. Run

\[
 \text{Pr}\left[\begin{array}{c}
 \mu_0 \xleftarrow{\$} \{0, 1\}^\lambda, \\
 \mu_1 \xleftarrow{\$} \{0, 1\}^\lambda \\
 \beta \xleftarrow{\$} \{0, 1\} \\
 \text{ct} \xleftarrow{\$} \text{Enc}(1^\lambda, \{pk^*_j\}_{j \in [N]}, \mu_\beta)
\end{array}\right] = \mathcal{D}(\mu_0, \mu_1, \text{ct}) = \beta - \frac{1}{2} \geq \epsilon^*;
\]

- and **NotFound** the event that \(i^* \notin [N]\) (i.e., \(i^* = \perp\)).

\(\mathcal{B}\) wins if and only if \(\text{FalsePos} \lor (\text{GoodDist} \land \text{NotFound})\).

AH-BTR as defined above is a key-encapsulation mechanism, following [Zha20a]. Using with traceability under adversarially chosen messages. As noted in Remark 3 of [Zha20b], traceability implies KEM security (or IND-CPA when combined with hybrid encryption).
Theorem 2 (¶). An AH-BTR scheme is traceable if and only if it is both complete and sound.

Proof (Theorem 2). The reductionist proof of necessity is straightforward — the query phase is unused by the reduction algorithm for completeness, and used only for creating the public key given to the adversary as input for soundness.

To show sufficiency, suppose the AH-BTR scheme \((\text{Gen}, \text{Enc}, \text{Dec}, \text{Trace})\) is both complete and sound and let \(\mathcal{B}\) be an efficient adversary against its traceability. We consider two efficient adversaries. \(\mathcal{C}_1\) is against the completeness of the scheme. It works by internally simulating the traceability game for \(\mathcal{B}\) and outputting whatever \(\mathcal{B}\) outputs. To show sufficiency, suppose the AH-BTR scheme \((\text{Gen}, \text{Enc}, \text{Dec}, \text{Trace})\) is both complete and sound and let \(\mathcal{B}\) be an efficient adversary against its traceability. Consider the coupling between \(\text{Exp}_{\text{complete}}\) for \(\mathcal{C}_1\) and the simulated \(\text{Exp}_{\text{trace}}\) for \(\mathcal{B}\) inside, writing the events for adversary \(\mathcal{X}\) in its security experiment with subscript \(\mathcal{X}\),

\[
\text{GoodDist}_{\mathcal{C}_1} \iff \text{GoodDist}_{\mathcal{B}} \quad \text{and} \quad \text{NotFound}_{\mathcal{C}_1} \iff \text{NotFound}_{\mathcal{B}}.
\]

Therefore,

\[
\Pr[\text{GoodDist}_{\mathcal{B}} \land \text{NotFound}_{\mathcal{B}}] = \Pr[\text{GoodDist}_{\mathcal{C}_1} \land \text{NotFound}_{\mathcal{C}_1}].
\]

\(\mathcal{C}_2\) is against the soundness of the scheme. Let \(B = \text{poly}(\lambda) > 1\) be an upper bound of the running time of \(\mathcal{B}\). The adversary \(\mathcal{C}_2\) does the following:

- \(\mathcal{C}_2(\text{pk})\) launches \(\mathcal{B}\), initializes \(S\) to \(\varnothing\), lets \(Q \leftarrow 0\), and samples and sets \(s^* \overset{\$}{\leftarrow} [B], \text{pk}^*_s, \leftarrow \text{pk}, (\text{pk}_t, \text{sk}_t) \overset{\$}{\leftarrow} \text{Gen}()\) for \(t \in [B] \setminus \{s^*\}\).

- \(\mathcal{C}_2\) answers queries from \(\mathcal{B}\) and updates \(Q, S\) as stipulated by the query phase of the traceability experiment, except that it aborts if \(\mathcal{B}\) queries for \(\text{sk}^*_s\).

- After the query phase, \(\mathcal{B}\) outputs \(\mathcal{D}, \{\text{pk}^*_j\}_{j \in [N]}, 1^{1/\varepsilon^*}\), and \(\mathcal{C}_2\) samples or sets \(i^*_\perp \leftarrow \begin{cases} \mathcal{I}^*_\perp, & \text{if } \mathcal{I}^*_\perp \leftarrow \{ i \in [N] : \text{pk}^*_i = \text{pk} \} \neq \varnothing; \\ \perp, & \text{otherwise}. \end{cases}\)

  It aborts if \(i^*_\perp = \perp\). Otherwise, \(\mathcal{C}_2\) outputs \(\mathcal{D}, \; N, \; i^*_\perp, \; \{\text{pk}^*_j\}_{j \in [N] \setminus \{i^*_\perp\}}, \; 1^{1/\varepsilon^*}\).

Consider the coupling between \(\text{Exp}_{\text{sound}}\) for \(\mathcal{C}_2\) and the simulated \(\text{Exp}_{\text{trace}}\) for \(\mathcal{B}\) inside. Routine calculation yields

\[
\Pr[\text{FalsePos}_{\mathcal{C}_2}] \geq \frac{1}{B^2} \Pr[\text{FalsePos}_{\mathcal{B}}].
\]

By the union bound,

\[
\Pr[\text{FalsePos}_{\mathcal{B}} \lor (\text{GoodDist}_{\mathcal{B}} \land \text{NotFound}_{\mathcal{B}})] \\
\leq \Pr[\text{FalsePos}_{\mathcal{B}}] + \Pr[\text{GoodDist}_{\mathcal{B}} \land \text{NotFound}_{\mathcal{B}}] \\
\leq B^2 \Pr[\text{FalsePos}_{\mathcal{C}_2}] + \Pr[\text{GoodDist}_{\mathcal{C}_1} \land \text{NotFound}_{\mathcal{C}_1}] \\
= (\text{poly}(\lambda))^2 \text{negl}(\lambda) + \text{negl}(\lambda) = \text{negl}(\lambda). \quad \Box
\]
4 Ad Hoc Private Linear Broadcast Encryption

Our construction of AH-BTR follows that of traitor tracing schemes in [BSW06]. We define ad hoc private broadcast linear encryption (AH-PLBE) by adapting the notion of PLBE [BSW06] to the ad hoc setting.

Definition 15 (AH-PLBE). An ad hoc private linear broadcast encryption (AH-PLBE) scheme (with message space \(\{0, 1\}^\lambda\) and public key length \(M_0(\lambda)\)) consists of 3 efficient algorithms:

- \(\text{Gen}(1^\lambda)\) outputs a pair \((\text{pk}, \text{sk})\) of public and secret keys with \(|\text{pk}| = M_0(\lambda)\).
- \(\text{Enc}(1^\lambda, \{\text{pk}_j\}_{j \in [N]}, i_\perp \in [0..N], \mu \in \{0, 1\}^\lambda\) takes as input a list of public keys, a cut-off index, and a message. It outputs a ciphertext \(ct\).
- \(\text{Dec}(\text{pk}_j)_{j \in [N]} \cdot \text{ct}(1^\lambda, N, i \in [N], \text{sk}_i)\) is given random access to a list of public keys and a ciphertext, and takes as input the length of the list, an index, and a secret key. It outputs a message.

The scheme must be robustly correct, i.e., for all \(\lambda \in \mathbb{N}\), \(N \in \mathbb{N}\), \(i \in [N]\), \(\{\text{pk}_j\}_{j \in [N] \setminus \{i\}}\)\(^{12}\) such that \(|\text{pk}_j| = M_0(\lambda)\) for all \(j \in [N] \setminus \{i\}\), and \(\mu \in \{0, 1\}^\lambda\),

\[\Pr \left[ (\text{pk}_i, \text{sk}_i) \xleftarrow{\$} \text{Gen}(1^\lambda) \right. \left. \right. \right. \left. \text{ct} \xleftarrow{\$} \text{Enc}(1^\lambda, \{\text{pk}_j\}_{j \in [N]}, 0, \mu) \mid \text{Dec}(\text{pk}_j)_{j \in [N]} \cdot \text{ct}(1^\lambda, N, i, \text{sk}_i) = \mu \right] = 1.\]

Security. We define security notions of AH-PLBE analogously to those in [BSW06], except “mode indistinguishability” (Game 1 in [BSW06]), which is for private tracing thus not needed here (public tracing). The two security definitions have a one-to-one correspondence to the simplified security notions of AH-BTR in Section 3.1. Namely, message-hiding translates to completeness, and index-hiding translates to soundness.

Definition 16 (message-hiding). An AH-PLBE scheme \((\text{Gen}, \text{Enc}, \text{Dec})\) per Definition 15 is message-hiding if \(\text{Exp}_{\text{MH}}^0 \approx \text{Exp}_{\text{MH}}^1\), where \(\text{Exp}_{\text{MH}}^i(1^\lambda)\) with adversary \(\mathcal{A}\) proceeds as follows:

- **Challenge.** \(\mathcal{A}(1^\lambda)\) and receive from it a list \(\{\text{pk}_j\}_{j \in [N]}\) of public keys. Run
  \[\mu_0 \xleftarrow{\$} \{0, 1\}^\lambda, \quad \mu_1 \xleftarrow{\$} \{0, 1\}^\lambda, \quad \text{ct} \xleftarrow{\$} \text{Enc}(1^\lambda, \{\text{pk}_j\}_{j \in [N]}, N, \mu_b),\]
  and send \((\mu_0, \mu_1, \text{ct})\) to \(\mathcal{A}\).
- **Guess.** \(\mathcal{A}\) outputs a bit \(b',\) which is the output of the experiment.

Definition 17 (index-hiding). An AH-PLBE scheme \((\text{Gen}, \text{Enc}, \text{Dec})\) per Definition 15 is index-hiding if \(\text{Exp}_{\text{IH}}^0 \approx \text{Exp}_{\text{IH}}^1\), where \(\text{Exp}_{\text{IH}}^i(1^\lambda)\) with adversary \(\mathcal{A}\) proceeds as follows:

- **Challenge.** Run \((\text{pk}, \text{sk}) \xleftarrow{\$} \text{Gen}(1^\lambda), \) launch \(\mathcal{A}(1^\lambda, \text{pk})\), which chooses some \(N \in \mathbb{N}\), a cut-off index \(i^*_\perp \in [N]\), and a list \(\{\text{pk}_j\}_{j \in [N] \setminus \{i^*_\perp\}}\) of public keys. Let \(\text{pk}_j \leftarrow \text{pk}\), run
  \[\mu \xleftarrow{\$} \{0, 1\}^\lambda, \quad \text{ct} \xleftarrow{\$} \text{Enc}(1^\lambda, \{\text{pk}_j\}_{j \in [N]}, i^*_\perp - 1 + b, \mu),\]
  and send \((\mu, \text{ct})\) to \(\mathcal{A}\).
- **Guess.** \(\mathcal{A}\) outputs a bit \(b',\) which is the output of the experiment.

\(^{12}\)These public keys could be out of the support of \(\text{Gen}\), i.e., malformed.
4.1 Construction

Ingredients of Construction 1. Let

- \( \text{GC} = (\text{GC.Garble, GC.Eval, GC.SimGarble}) \) be a circuit garbling scheme such that its
  \( \text{GC.Garble} \) uses \( \lambda \)-bit randomness,
- \( \text{PPRF} = (\text{PPRF.Puncture, PPRF.Eval}) \) a PPRF,
- \( \text{PKE} = (\text{PKE.Gen, PKE.Enc, PKE.Dec}) \) a PKE scheme such that its \( \text{PKE.Enc} \) uses
  \( \lambda \)-bit randomness and its public keys are (exactly) of polynomial length \( M_0 \),
- \( \text{LOT} = (\text{LOT.Gen, LOT.Hash, LOT.Send, LOT.Recv}) \) a laconic OT scheme,
- \( \text{Obf} \) an obfuscator.

Construction 1 (AH-PLBE). Our AH-PLBE works as follows:

- \( \text{Gen} \) is the same as \( \text{PKE.Gen} \).
- \( \text{Enc}((\{pk_j\})_{j \in [N]}, i_\perp, \mu) \) first checks whether \( |pk_j| = M_0 \) for all \( j \in [N] \). If not, it
  outputs \( \text{ct} = \perp \) and terminates. Otherwise, the algorithm hashes down the public
  keys by running
  \[
  M \leftarrow NM_0, \quad D \leftarrow pk_1 \cdots pk_N, \\
  hk \leftarrow \text{LOT.Gen}(M), \quad (h, \tilde{D}) \leftarrow \text{LOT.Hash}(hk, D).
  \]

It samples a placeholder message \( \mu_\perp \leftarrow \{0,1\}^\lambda \) and PPRF keys
\[
  k^\text{GC} \leftarrow \{0,1\}^\lambda, \quad k^\text{PKE} \leftarrow \{0,1\}^\lambda, \quad k^\text{LOT} \leftarrow \{0,1\}^\lambda \quad \text{for } m_0 \in [M_0],
\]
and obfuscates \( C^\text{GC} \) (Figure 1) by running
\[
  \tilde{C}^\text{GC} \leftarrow \text{Obf}(C^\text{GC}(N, hk, h, i_\perp, \mu_\perp, \mu, k^\text{GC}, k^\text{PKE}, \{k^\text{LOT}_{m_0}\}_{m_0 \in [M_0]})).
\]
The algorithm outputs \( \text{ct} = (hk, \tilde{C}^\text{GC}) \) as the ciphertext.

- \( \text{Dec}(pk_j)_{j \in [N], \text{ct}((N, i, sk_i))} \) first parses \( \text{ct} = (hk, \tilde{C}^\text{GC}) \) and recomputes
  \[
  M \leftarrow NM_0, \quad D \leftarrow pk_1 \cdots pk_N, \quad (h, \tilde{D}) \leftarrow \text{LOT.Hash}(hk, D).
  \]
The algorithm next runs the obfuscated circuit,
\[
  (\tilde{C}_{ct, i}, \{\text{LOT.ct}_{i, m_0}\}_{m_0 \in [M_0]}) \leftarrow \tilde{C}^\text{GC}(i),
\]
to obtain the garbled \( C_{ct} \) (Figure 1) for the decryptor and the laconic OT ciphertexts
sending its labels. It then receives the labels,
\[
  L_{i, m_0, pk_{[m_0]}} \leftarrow \text{LOT.Recv}(hk, h, (i - 1)M_0 + m_0, \text{LOT.ct}_{i, m_0}) \quad \text{for } m_0 \in [M_0],
\]
and evaluates the garbled circuit,
\[
  \text{PKE.ct}_{i} \leftarrow \text{GC.Eval}(\tilde{C}_{ct, i}, pk_i, [L_{i, m_0, pk_{[m_0]}}]_{m_0 \in [M_0]}),
\]
to obtain the PKE ciphertext under the decryptor’s public key. Lastly, the algorithm
runs and outputs (as the decrypted message)
\[
  \mu \leftarrow \text{PKE.Dec}(sk_i, \text{PKE.ct}_{i}).
\]
\[
C_{GC}[N, hk, h, i_\perp, \mu_\perp, \mu, k_{GC}, k_{PKE}, \{k_{LOT}^m\}_{m_0 \in [M_0]}](i)
\]

**Hardwired.**

- \( N \), number of users;
- \( hk \), laconic OT hash key;
- \( h \), laconic OT hash of \( D = pk_1 \| \cdots \| pk_N \);
- \( i_\perp \), cut-off index;
- \( \mu_\perp \), placeholder message;
- \( \mu \), message;
- \( k_{GC} \), PPRF key for circuit garbling;
- \( k_{PKE} \), PPRF key for public-key encryption;
- \( k_{LOT}^m \), PPRF key for sending the \( m_0^{th} \) label using laconic OT.

**Input.**

- \( i \in [N] \), index of recipient.

**Output.** Computed as follows.

\[
\begin{align*}
    r_{i_{GC}}^i &\leftarrow \text{PPRF.Eval}(k_{GC}, i) \\
    r_{i_{PKE}}^i &\leftarrow \text{PPRF.Eval}(k_{PKE}, i) \\
    r_{i_{LOT}}^i &\leftarrow \text{PPRF.Eval}(k_{LOT}^m, i) \quad \text{for} \quad m_0 \in [M_0] \\
    (\tilde{C}_{ct,i}, \{L_{i,m_0,b}\}_{m_0 \in [M_0], b \in \{0,1\}}) &\leftarrow \begin{cases} 
    \text{GC.Garble}(\tilde{C}_{ct}, (\mu_\perp, r_{i_{PKE}}^i); r_{i_{GC}}^i), & \text{if} \quad i \leq i_\perp; \\
    \text{GC.Garble}(\tilde{C}_{ct}, (\mu, r_{i_{PKE}}^i); r_{i_{GC}}^i), & \text{if} \quad i > i_\perp;
    \end{cases}
\end{align*}
\]

\[
\text{LOT.ct}_{i,m_0} \leftarrow \text{LOT.Send}(hk, h, (i-1)M_0 + m_0, L_{i,m_0,0}, L_{i,m_0,1}; r_{i_{LOT}}^i) \quad \text{for} \quad m_0 \in [M_0]
\]

**Output** \( (\tilde{C}_{ct,i}, \{\text{LOT.ct}_{i,m_0}\}_{m_0 \in [M_0]}) \)

**Hardwired.**

- \( \mu_i' \), message or placeholder message;
- \( r_{i_{PKE}}^i \), public-key encryption randomness.

**Input.** \( pk_i \), public key of recipient.

**Output.** \( \text{PKE.ct}_{i} \leftarrow \text{PKE.Enc}(pk_i, \mu_i'; r_{i_{PKE}}^i) \).

**Figure 1:** The circuits \( C_{GC} \) and \( C_{ct} \) in Construction 1.

**Robust Correctness.** It follows from the correctness of the ingredients.

**Efficiency.** By laconic OT efficiency, the call to \( \text{LOT.Gen} \) takes time \( \text{poly}(\lambda, \log(N + 1)) \), that to \( \text{LOT.Hash} \) takes time \( (N+1) \text{poly}(\lambda, \log(N+1)) \), and \( |hk|, |h| = \text{poly}(\lambda, \log(N + 1)) \).

As we shall see later, it suffices to pad \( C_{GC} \) to size \( \text{poly}(\lambda, \log(N + 1)) \) for the security proofs to go through. Putting these together,

\[
T_{Enc}, T_{Dec} = (N + 1) \text{poly}(\lambda, \log(N + 1)), \quad |ct| = \text{poly}(\lambda, \log(N + 1)).
\]

In practice and for security reasons, we always assume \( N \leq 2^\lambda \) and \( \log(N + 1) \) is absorbed by \( \lambda \). Therefore, with \( \text{poly}(\lambda) \) factors ignored, both encryption and decryption take linear time, and the ciphertext is constant-size.

\(^{13}\)A scheme can always set the ciphertext to the message itself whenever \( N > 2^\lambda \) and remain correct and asymptotically secure. See also Footnote 7.
Compatibility. Since the key generation algorithm of Construction 1 is just the key generation algorithm of the underlying PKE scheme (which only has to be semantically secure for random messages), it is compatible with the existing public-key encryption schemes, i.e., existing users possessing PKE key pairs can utilize our AH-PLBE without regenerating their keys.

4.2 Security

Theorem 3 (\textcircled{3}). Suppose in Construction 1, the obfuscator Obf is an $iO$ for poly($\lambda$)-sized domain, then the resultant AH-PLBE is message-hiding.

Theorem 4 (\textcircled{4}). Suppose in Construction 1, all of the ingredients are secure, then the resultant AH-PLBE is index-hiding.

Proof (Theorem 3). For Construction 1, the only difference between Exp$^0_{\text{MH}}$ and Exp$^1_{\text{MH}}$ is whether $C_{\text{GC}}$ used to create $ct = (hk, \hat{C}_{\text{GC}})$ has $\mu_0$ or $\mu_1$ hardwired as $\mu$. In $C_{\text{GC}}$ (Figure 1), $\mu$ is used only in the branch $i > i_1$, which is never taken in Exp$^0_{\text{MH}}$ or Exp$^1_{\text{MH}}$ because $i_1$ is hardwired to be $N$ and the domain of $i$ is $[N]$. Therefore, the two $C_{\text{GC}}$'s in Exp$^0_{\text{MH}}$ and Exp$^1_{\text{MH}}$ being obfuscated are functionally equivalent and have the same size. Moreover, their domain size is $N$ (polynomially large). Therefore, Exp$^0_{\text{MH}} \approx$ Exp$^1_{\text{MH}}$ reduces to the iO security for poly($\lambda$)-sized domain of Obf.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{The circuit $C'_{\text{GC}}$ in the proof of Theorem 4.}
\end{figure}
Proof (Theorem 4). The only difference between $\text{Exp}_b^0$ and $\text{Exp}_b^1$ is whether the $C_{\text{GC}}$ being obfuscated hardwires $\mu$ (in $\text{Exp}_b^0$) or $\mu_\bot$ (in $\text{Exp}_b^1$) into $C_{\text{ct},i_\bot^*}$, which only affects the output of $C_{\text{GC}}$ at $i = i_{\bot}^*$. We consider the following hybrids, each (except the first) described by the changes from the previous one:

- $H_b^0$ (for $b \in \{0,1\}$) is $\text{Exp}_b^1$, where

\[
\begin{align*}
\text{hk} & \leftarrow \text{LOT.Gen}(N, M_0), \quad (h, \hat{D}) \leftarrow \text{LOT.Hash}((hk, \text{pk}_1^* \| \cdots \| \text{pk}_N^*)), \\
k_{\text{GC}} & \leftarrow \{0,1\}^\lambda, \quad k_{\text{PKE}} \leftarrow \{0,1\}^\lambda, \quad k_{\text{PKE},0} \leftarrow \{0,1\}^\lambda \text{ for } m_0 \in [M_0], \\
\tilde{C}_{GC} & \leftarrow \text{Obf}(C_{GC}[N, hk, h, i_{\bot}^* - 1 + b, \mu_\bot, \mu, k_{GC}, k_{\text{PKE}}, \{i_{\bot}^*\}_m\in[M_0])), \\
c_t = (hk, \tilde{C}_{GC}).
\end{align*}
\]

- $H_b^1$ alters the obfuscation into

\[
\begin{align*}
\tilde{C}_{GC} & \leftarrow \text{Obf}(C_{GC}'[N, hk, h, \mu_\bot, \mu,\]
\begin{align*}
& i_{\bot}^*, k_{GC}^{i_{\bot}^*}, k_{\text{PKE}}^{i_{\bot}^*}, \{k_{\text{PKE},0,i_{\bot}^*}\}_m\in[M_0], \tilde{C}_{\text{ct},i_{\bot}^*}, \{\text{LOT.ct}_{i_{\bot}^*,m_0}\}_m\in[M_0]),
\end{align*}
\]

where

- $C_{GC}'$ is defined in Figure 2,
- the PPRF keys are punctured at $i_{\bot}^*$ by running

\[
\begin{align*}
k_{GC}^{i_{\bot}^*} & \leftarrow \text{PPRF.Puncture}(k_{GC}, i_{\bot}^*), \\
k_{\text{PKE}}^{i_{\bot}^*} & \leftarrow \text{PPRF.Puncture}(k_{\text{PKE}}, i_{\bot}^*), \\
k_{\text{PKE},0}^{i_{\bot}^*} & \leftarrow \text{PPRF.Puncture}(k_{\text{PKE},0}, i_{\bot}^*) \quad \text{for } m_0 \in [M_0],
\end{align*}
\]

- and the output $(\tilde{C}_{\text{ct},i_{\bot}^*}, \{\text{LOT.ct}_{i_{\bot}^*,m_0}\}_m\in[M_0])$ of $C_{GC}'$ at $i = i_{\bot}^*$ is computed as

\[
\begin{align*}
\text{r}_{GC} & \leftarrow \text{PPRF.Eval}(k_{GC}, i_{\bot}^*), \\
\text{r}_{\text{PKE}} & \leftarrow \text{PPRF.Eval}(k_{\text{PKE}}, i_{\bot}^*) , \\
\text{r}_{\text{PKE},0} & \leftarrow \text{PPRF.Eval}(k_{\text{PKE},0}, i_{\bot}^*) \quad \text{for } m_0 \in [M_0], \\
(\tilde{C}_{\text{ct},i_{\bot}^*}, \{L_{i_{\bot}^*,m_0,b}\}_m\in[M_0],b\in\{0,1\}) & \leftarrow \left\{
\begin{align*}
\text{GC.Garble} & (C_{\text{ct}, \mu, r_{\text{GC},i_{\bot}^*}, i_{\bot}^*}), \quad \text{if } b = 0; \\
\text{GC.Garble} & (C_{\text{ct}, \mu, r_{\text{PKE},i_{\bot}^*}, i_{\bot}^*}), \quad \text{if } b = 1;
\end{align*}
\right.
\end{align*}
\]

\[
\text{LOT.ct}_{i_{\bot}^*,m_0} \leftarrow \text{LOT.Send}((hk, h, (i_{\bot}^* - 1)M_0 + m_0), \\
L_{i_{\bot}^*,m_0,0}, L_{i_{\bot}^*,m_0,1}; \text{r}_{\text{PKE},0}^{i_{\bot}^*}) \quad \text{for } m_0 \in [M_0].
\]

- $H_b^2$ changes $\text{r}_{GC}, \text{r}_{\text{PKE}}, \text{r}_{\text{PKE},0}$'s into true randomness, i.e.,

\[
\begin{align*}
\text{r}_{GC} & \leftarrow \{0,1\}^\lambda, \quad \text{r}_{\text{PKE}} \leftarrow \{0,1\}^\lambda, \quad \text{r}_{\text{PKE},0} \leftarrow \{0,1\}^\lambda \quad \text{for } m_0 \in [M_0].
\end{align*}
\]

- $H_b^3$ removes the unused labels from $\text{LOT.ct}_{i_{\bot}^*,m_0}$'s by setting

\[
\begin{align*}
\text{LOT.ct}_{i_{\bot}^*,m_0} & \leftarrow \text{LOT.Send}((hk, h, (i_{\bot}^* - 1)M_0 + m_0), \\
L_{i_{\bot}^*,m_0,\text{pk}_{i_{\bot}^*}} (m_0), L_{i_{\bot}^*,m_0,\text{pk}_{i_{\bot}^*}} (m_0); \text{r}_{\text{PKE},0}^{i_{\bot}^*}) \quad \text{for } m_0 \in [M_0].
\end{align*}
\]
Claim 5. $H^0_b \approx H^1_b$ for $b \in \{0,1\}$ if $\text{Obf}$ is an $iO$ for $\text{poly}(\lambda)$-sized domain.

Claim 6. $H^1_b \approx H^2_b$ for $b \in \{0,1\}$ if $\text{PPRF}$ is pseudorandom at the punctured point.

Claim 7. $H^2_b \approx H^3_b$ for $b \in \{0,1\}$ if $\text{LOT}$ is database-selectively sender-private.

Claim 8. $H^3_b \approx H^4_b$ for $b \in \{0,1\}$ if $\text{GC}$ is $w$-hiding.

Claim 9. $H^4_b \approx H^5_b$ if $\text{PKE}$ is semantically secure for random messages.

$\text{Exp}^0_H \approx \text{Exp}^1_H$ follows from a hybrid argument.

5 AH-BTR from AH-PLBE

Ingredient of Construction 2. Let $\text{ahPLBE} = (\text{ahPLBE.Gen}, \text{ahPLBE.Enc}, \text{ahPLBE.Dec})$ be an AH-PLBE scheme.

Construction 2 (adapted from [BSW06; Section 2.2]). Our AH-BTR works as follows:

- Gen is the same as $\text{ahPLBE.Gen}$.
- Enc($\{pk_j\}_{j \in [N]}, \mu$) runs and outputs $ct \leftarrow \text{ahPLBE.Enc}(\{pk_j\}_{j \in [N]}, 0, \mu)$.
- Dec is the same as $\text{ahPLBE.Dec}$.
- Trace$^D(\{pk^*_j\}_{j \in [N]}, N, 1/\epsilon^*)$ defines for $i \in [0..N]$,

$$
\varepsilon_i = \text{Pr}(\text{ct} \leftarrow \text{ahPLBE.Enc}(\{pk^*_j\}_{j \in [N]}, i, \beta) \mid D(\mu_0, \mu_1, \text{ct}) = \beta) - \frac{1}{2}.
$$

Setting $\delta \leftarrow \frac{\epsilon^*}{10N}$ and $\eta \leftarrow \frac{1}{2 \delta} \log(2N + 2)$, for each $i \in [0..N]$, the algorithm runs $\varepsilon_i$ for $\eta$ times independently, counts the absolute frequency $\xi_i \in [0..\eta]$ of $E_i$, and computes $\hat{\xi}_i = \frac{\xi_i}{\eta} - \frac{1}{2}$. It outputs

$$
i^* = \begin{cases} 
\min T, & \text{if } T \leftarrow \{ i \in [N] : |\hat{\xi}_i - \hat{\xi}_{i-1}| \geq 3\delta \} \neq \emptyset; \\
\bot, & \text{if } T = \emptyset.
\end{cases}
$$

Robust Correctness, Efficiency, Compatibility. These are inherited from the underlying AH-PLBE. When based on Construction 1, the resultant AH-BTR has

$$
T_{\text{Enc}} = (N + 1) \text{poly}(\lambda), \quad |ct| = \text{poly}(\lambda), \quad T_{\text{Dec}} = (N + 1) \text{poly}(\lambda),
$$

and is compatible with the existing public-key encryption schemes.
**Theorem 10 (¶).** Suppose in Construction 2, the AH-PLBE scheme ahPLBE is message-hiding, then the resultant AH-BTR is sound.

**Theorem 11 (¶).** Suppose in Construction 2, the AH-PLBE scheme ahPLBE is index-hiding, then the resultant AH-BTR is sound.

**Proof** (Theorem 10). Consider any efficient adversary \( C \) against the completeness of Construction 2. Let \( \text{GoodEst} \) be the event that \( |\tilde{e}_i - e_i| \leq \delta \) for all \( i \in [0..N] \). By the Chernoff bound, the union bound, and the law of total probability,

\[
\Pr[\text{\neg GoodEst}] = \mathbb{E}[\Pr[\text{\neg GoodEst} | \epsilon^*, N]] \leq \mathbb{E}[2(N + 1) \exp(-2\delta^2\eta)] \leq 2^{-\lambda}.
\]

Let \( \text{BadEnd} \) be the event that \( |\varepsilon_N| > \frac{\epsilon^*}{2} \), then \( \text{GoodDist} \land \text{\neg BadEnd} \) implies

\[
\max_{i \in [N]} |\tilde{e}_{i-1} - e_i| \geq \frac{1}{N} \sum_{i=1}^{N} |\tilde{e}_{i-1} - e_i| \geq \frac{1}{N} \sum_{i=1}^{N} (\varepsilon_{i-1} - \varepsilon_i) \geq \frac{1}{N} |\varepsilon_0 - \varepsilon_N| \geq \frac{1}{2} (|\varepsilon_0| - |\varepsilon_N|) \geq \frac{1}{2} \left( \frac{\epsilon^* - \epsilon^*}{2} \right) = \frac{\epsilon^*}{2N} = 5\delta,
\]

Therefore, \( \text{GoodDist} \land \text{\neg BadEnd} \land \text{GoodEst} \) implies

\[
\max_{i \in [N]} |\tilde{e}_{i-1} - e_i| \geq \max_{i \in [N]} (|\varepsilon_{i-1} - \varepsilon_i| - 2\delta) \geq 5\delta - 2\delta = 3\delta,
\]

which in turn implies \( T \neq \emptyset \) hence \( i^* \in [N] \), i.e., \( \text{\neg NotFound} \). By contraposition,

\[
\text{GoodDist} \land \text{NotFound} \land \text{GoodEst} \implies \text{BadEnd}.
\]

By the union bound,

\[
\Pr[C \text{ wins}] \leq \Pr[\text{\neg GoodEst}] + \Pr[(C \text{ wins}) \land \text{GoodEst}]
\]

\[
= \Pr[\text{\neg GoodEst}] + \Pr[\text{GoodDist} \land \text{NotFound} \land \text{GoodEst}]
\]

\[
\leq 2^{-\lambda} + \Pr[\text{BadEnd}],
\]

so it remains to show \( \Pr[\text{BadEnd}] = \text{negl}(\lambda) \).

Consider the following efficient adversary \( A \) against the message-hiding property of ahPLBE:

- \( A \) runs \( C \) to obtain \( D, \{pk_j^*\}_{j \in [N]}, 1^{1/\varepsilon^*} \).

- \( A \) runs \( E_N \) once and notes down \( \alpha \in \{0, 1\} \) indicating whether \( E_N \) happened, i.e., \( \alpha = 1 \) if and only if \( D \) guessed correctly in the trial.

- \( A \) submits \( \{pk_j^*\}_{j \in [N]} \) to the message-hiding experiment, receives \( (\mu_0, \mu_1, \text{ct}) \) back, and runs and outputs \( b' \leftarrow D(\mu_0, \mu_1, \text{ct}) \oplus \alpha \).

Routine calculation shows that the advantage of \( A \) is \( \mathbb{E}[4\varepsilon_N^2] \), which must be negligible by the message-hiding property of ahPLBE. Let \( B = \text{poly}(\lambda) \) be an upper bound of \( 1/\varepsilon^* \) (\( B \) exists since \( C \) outputs \( 1^{1/\varepsilon^*} \) in polynomial time). By Markov’s inequality,

\[
\Pr[\text{BadEnd}] = \Pr[4\varepsilon_N^2 > (\varepsilon^*)^2] \leq \Pr[4\varepsilon_N^2 > B^{-2}]
\]

\[
\leq B^2 \mathbb{E}[4\varepsilon_N^2] = (\text{poly}(\lambda))^2 \text{negl}(\lambda) = \text{negl}(\lambda).
\]
Proof (Theorem 11). Consider any efficient adversary $C$ against the soundness of Construction 2. Similarly to the proof of Theorem 10, define $\text{GoodEst}$ and recall that $\Pr[\neg \text{GoodEst}] \leq 2^{-\lambda}$. We have

$$
\Pr[C \text{ wins}] \leq \Pr[\neg \text{GoodEst}] + \Pr[(C \text{ wins}) \land \text{GoodEst}]
= \Pr[\neg \text{GoodEst}] + \Pr[\text{FalsePos} \land \text{GoodEst}]
\leq 2^{-\lambda} + \Pr[\text{FalsePos} \land \text{GoodEst}],
$$

and it suffices to prove $\Pr[\text{FalsePos} \land \text{GoodEst}] = \text{negl}(\lambda)$.

Let $\alpha$ be a random element in an execution of $\text{Trace}$ with

$$
\alpha = \begin{cases} 
0, & \text{if } i^* \in [N] \text{ and } \hat{\epsilon}_{i^*} - \hat{\epsilon}_{i^*} \geq 3\delta; \\
1, & \text{if } i^* \in [N] \text{ and } \hat{\epsilon}_{i^*} - \hat{\epsilon}_{i^*} \leq -3\delta; \\
\perp, & \text{if } i^* = \perp.
\end{cases}
$$

Consider the following efficient adversary $A$ against the index-hiding property of $\text{ahPLBE}$:

- $A(pk)$ runs $C(pk)$ to obtain
  $$
  D, \quad N, \quad i^*_1, \quad \{pk_j^*\}_{j \in [N] \setminus \{i^*_1\}}, \quad 1^{1/\varepsilon^*},
  $$
  and sets $pk_{i^*_1}^* \leftarrow pk$.

- $A$ runs
  $$
  i^* \leftarrow \text{Trace}^D(\{pk_j^*\}_{j \in [N]}, 1^{1/\varepsilon^*}),
  $$
  and aborts if $i^* \neq i^*_1$.

- $A$ notes down $\alpha \in \{0, 1\}$ from the above execution of $\text{Trace}$, submits
  $$
  N, \quad i^*_1, \quad \{pk_j^*\}_{j \in [N] \setminus \{i^*_1\}}
  $$
  to the index-hiding experiment, gets $(\mu, ct)$ back, samples and sets
  $$
  \beta \leftarrow \{0, 1\}, \quad \mu_{\beta} \leftarrow \mu, \quad \mu_{\perp} \leftarrow \{0, 1\}^\lambda,
  $$
  and runs and outputs $b' \leftarrow D(\mu_0, \mu_1, ct) \oplus \beta \oplus \alpha$.

Routine calculation shows that the advantage of $A$ is

$$
\mathbb{E}[\mathbb{1}_{\text{FalsePos}} \cdot (-1)^\alpha(\epsilon_{i^*} - \epsilon_{i^*})],
$$

which must be negligible by the index-hiding property of $\text{ahPLBE}$.

Let $B = \text{poly}(\lambda)$ be an upper bound of $10N/\varepsilon^*$ ($B$ exists since $C$ outputs $1^N$ and $1^{1/\varepsilon^*}$ in polynomial time). The event $\text{FalsePos} \land \text{GoodEst}$ implies

$$
(\varepsilon_{i^*} - \varepsilon_{i^*}) - (\hat{\epsilon}_{i^*} - \hat{\epsilon}_{i^*}) \leq 2\delta < 3\delta \leq |\varepsilon_{i^*} - \varepsilon_{i^*}| \\
\implies (-1)^\alpha(\varepsilon_{i^*} - \varepsilon_{i^*}) = |\varepsilon_{i^*} - \varepsilon_{i^*}| \geq 3\delta = \varepsilon^*/10N \geq B^{-1}.
$$

Moreover, $(-1)^\alpha(\varepsilon_{i^*} - \varepsilon_{i^*}) \geq -1$ always holds. These together show that

$$
\Pr[\text{FalsePos} \land \text{GoodEst}]
= B \mathbb{E}[\mathbb{1}_{\text{FalsePos}} \cdot \mathbb{1}_{\text{GoodEst}} \cdot B^{-1}]
\leq B \mathbb{E}[\mathbb{1}_{\text{FalsePos}} \cdot \mathbb{1}_{\text{GoodEst}} \cdot (-1)^\alpha(\varepsilon_{i^*} - \varepsilon_{i^*})]
$$
While Construction 2 achieves constant ciphertext size, it takes time $\Omega(N)$ to decrypt. In contrast, the naïve scheme that encrypts to each user separately has $\Omega(N)$-size ciphertext, yet decryption only takes constant time. By grouping the recipients and encrypting to each group separately, we can trade ciphertext size for decryption time.\footnote{Alternatively, one can reformulate Construction 2 as a compiler that trades decryption time for ciphertext size, by grouping the recipients and compressing the groups. We refrained from such a formulation because the “transformation” uses a quite strong additional assumption, namely functional encryption for general circuits.} Previous work \cite{Zha20a} already systemizes the idea of grouping in the context of traditional traitor tracing.

**Ingredients of Construction 3.** Let $\text{old} = (\text{old.Gen, old.Enc, old.Dec, old.Trace})$ be an AH-BTR scheme and $\gamma$ some\footnote{We require that $N \mapsto [N^\gamma]$ can be computed in (deterministic) time $\text{poly}(\log(N + 1))$.} constant ($0 < \gamma < 1$).

**Construction 3** (adapted from \cite{Zha20a; Theorem 1}). Our new AH-BTR works as follows:

- **Gen** is the same as old.Gen.
- **Enc**$(\{pk_j\}_{j \in [N]}, \mu)$ sets $N_1 = [N^\gamma]$ and $N_2 = [N/N_1]$. It runs

\[
\text{old.ct}_{j_i} \leftarrow \text{Enc}((pk_j)_{j < j_i \leq N_2}, \mu) \quad \text{for} \ j_i \in [N_1].
\]

The algorithm outputs $\text{ct} = \{\text{old.ct}_{j_i}\}_{j_i \in [N_1]}$.
- **Dec**$(pk_j)_{j \in [N]}, ct(N, i, sk_i)$ sets $N_1 = [N^\gamma], N_2 = [N/N_1]$. It parses $ct$ as in Enc, finds $i_1 \in [N_1]$ such that $(i_1 - 1)N_2 < i < i_1N_2$, and sets $N'_2 = \min\{N_2, N - (i_1 - 1)N_2\}$. The algorithm runs and outputs

\[
\text{old.Dec}(pk_j)_{j_1 < j < j_1 + N_2 \text{ old.ct}_{j_i}(N'_2, i - (i_1 - 1)N_2, sk_i)).
\]
- **Trace**$(\{pk_j\}_{j \in [N]}, 1^{|/\|})$ sets $N_1 = [N^\gamma]$ and $N_2 = [N/N_1]$. It runs

\[
i^*_1 \leftarrow \text{Trace}^{\text{old}}(pk_j)_{j_1 < j < j_1 + N_2, 1^{|/\|}} \quad \text{for} \ j_1 \in [N_1],
\]

where $D_{j_1}(\mu_0, \mu_1, \text{old.ct}^*)$ runs and outputs $D(\mu_0, \mu_1, \{\text{old.ct}_{j_1}\}_{j_1 \in [N_1]})$ with

\[
\begin{align*}
\text{old.ct}_{j_1} & \leftarrow \text{old.ct}^*, \\
\text{old.Enc}(\{pk_j\}_{j_1 < j < j_1 + N_2, \mu_1}) & \leftarrow \text{old.ct}^*.
\end{align*}
\]

The algorithm outputs

\[
\begin{cases}
(i - 1)N_2 + i_1, & \text{if } i_1^* = \bot \text{ for all } j_1^* < j_1 \text{ and } i_1^* \neq \bot; \\
\bot, & \text{if } i_1^* = \bot \text{ for all } j_1^* \in [N_1].
\end{cases}
\]
Robust Correctness and Compatibility. These are inherited from the underlying AH-BTR. When based on Construction 2, the resultant AH-BTR is compatible with the existing public-key encryption schemes.

Efficiency. Let $\gamma_1, \gamma_2, \gamma_3$ be constants such that the AH-BTR efficiency is

\[ T_{\text{Enc}} = (N+1)^{\gamma_1} \text{poly}(\lambda), \quad |\text{ct}| = (N+1)^{\gamma_2} \text{poly}(\lambda), \quad T_{\text{Dec}} = (N+1)^{\gamma_3} \text{poly}(\lambda), \]

then the underlying efficiency is mapped to the resultant efficiency\(^{16}\) by

\[ (\gamma_1, \gamma_2, \gamma_3) \mapsto (1 - \gamma + \gamma\gamma_1, 1 - \gamma + \gamma\gamma_2, \gamma\gamma_3). \]

When based on Construction 2, the resultant AH-BTR enjoys

\[ T_{\text{Enc}} = (N+1) \text{poly}(\lambda), \quad |\text{ct}| = (N+1)^{1-\gamma} \text{poly}(\lambda), \quad T_{\text{Dec}} = (N+1)^\gamma \text{poly}(\lambda). \]

Theorem 12 (\(*\)). Suppose in Construction 3, the underlying AH-BTR scheme old is complete, then so is the resultant AH-BTR.

Theorem 13 (\(*\)). Suppose in Construction 3, the underlying AH-BTR scheme old is sound, then so is the resultant AH-BTR.

Proof (Theorem 12). Let $C$ be an efficient adversary against the completeness of the resultant scheme. Consider the following efficient adversary $C_{\text{old}}$ against the completeness of old:

- $C_{\text{old}}$ launches $C$ to obtain
  \[ D, \quad \{pk_j^*\}_{j \in [N]}, \quad 1^{1/\varepsilon^*}. \]
  It computes $N_1, N_2$ as specified by the resultant scheme.

- $C_{\text{old}}$ samples $j^* \leftarrow [N_1]$, prepares $D_{j^*}$ (using $D$, as specified by the resultant scheme), and outputs
  \[ D_{j^*}, \quad \{pk_j^*\}_{(j^*-1)N_2 < j \leq j^*; N_2}, \quad 1^{N_1/\varepsilon^*}. \]

Let $B = \text{poly}(\lambda)$ be an upper bound of $N_1$. Routine calculation shows

\[ \Pr[C_{\text{old}} \text{ wins}] \geq \frac{1}{B} \Pr[C \text{ wins}], \]

hence by the completeness of old,

\[ \Pr[C \text{ wins}] \leq B \Pr[C_{\text{old}} \text{ wins}] = \text{poly}(\lambda) \text{ negl}(\lambda) = \text{negl}(\lambda). \]

Proof (Theorem 13). Let $C$ be an efficient adversary against the soundness of the resultant scheme. Consider the following efficient adversary $C_{\text{old}}$ against the soundness of old:

- $C_{\text{old}}(pk)$ launches $C(pk)$ to obtain
  \[ D, \quad N, \quad i^*_N, \quad \{pk_j^*\}_{j \in [N] \setminus \{i^*_N\}}, \quad 1^{1/\varepsilon^*}. \]
  It computes $N_1, N_2$ as specified by the resultant scheme.

- $C_{\text{old}}$ computes $j^*_1 = \lfloor i^*_N/N_2 \rfloor$ and outputs
  \[ D_{j^*_1}, \quad \min \{N_2, N - (j^*_1 - 1)N_2\}, \quad i^*_N - (j^*_1 - 1)N_2, \quad \{pk_j^*\}_{(j^*_1-1)N_2 < j \leq j^*_1; N_2, j \neq i^*_N}, \quad 1^{N_1/\varepsilon^*}. \]

Routine calculation and the soundness of old yield

\[ \Pr[C \text{ wins}] \leq \Pr[C_{\text{old}} \text{ wins}] = \text{negl}(\lambda). \]

\(^{16}\)We assume that old.ct's are of deterministic length so Dec knows the location of each particular old.ct. Alternatively, Enc can store a look-up table of their locations in ct.
7 Lower Bound on Ciphertext Size and Decryption Time

Ideally, we would like a scheme satisfying $|\text{ct}|, T_{\text{Dec}} = \Theta(1)$, yet curiously, even with the heavy hammer of obfuscation, we fail to achieve $|\text{ct}| \cdot T_{\text{Dec}} = o(N)$. It turns out that this limitation is inherent. In this section, we prove that for all secure AH-BTR,

$$|\text{ct}| \cdot T_{\text{Dec}} = \Omega(N),$$

and therefore, we have constructed all the optimal (ignoring poly($\lambda$) factors) AH-BTR schemes in this work, completely pinning down the Pareto front of its efficiency. In fact, we will show a related bound against a restricted kind of broadcast encryption, which the uniform and efficient approach against a restricted kind of broadcast encryption, which the uniform and efficient

Definition 18 (restricted broadcast encryption and its security). A restricted broadcast encryption (BE) scheme (for the purpose of this work) consists of 3 efficient algorithms:

- $\text{Gen}(1^\lambda, 1^N)$ takes a length parameter as input. It outputs a master public key $\text{mpk}$ and a list $\{\text{sk}_{j,s} \}_{j \in [N], s \in \{0,1\}}$ of secret keys.

- $\text{Enc}(1^\lambda, \text{mpk}, R, \mu)$ takes as input the master public key $\text{mpk}$, an $N$-bit string $R \in \{0,1\}^N$, and a message $\mu \in \{0,1\}^\lambda$. It outputs a ciphertext $\text{ct}_R$.

- $\text{Dec}^{\text{mpk}, i, r, \text{sk}_{i,r}}(\text{ct}_R)$ is given random access to the master public key $\text{mpk}$, a secret key with its description $(i, r, \text{sk}_{i,r})$, a ciphertext with its attribute $(R, \text{ct}_R)$. It is supposed to recover $\mu$ if and only if $R[i] = r$.

The scheme must be correct, i.e., for all $\lambda, N \in \mathbb{N}$, $R \in \{0,1\}^N$, $i \in [N]$, $\mu \in \{0,1\}^\lambda$,

$$\Pr \left[ \left( \text{mpk}, \{\text{sk}_{j,s} \}_{j \in [N], s \in \{0,1\}} \right) \xleftarrow{} \text{Gen}(1^\lambda, 1^N) ; \text{ct}_R \xleftarrow{} \text{Enc}(1^\lambda, \text{mpk}, R, \mu) ; \text{Dec}^{\text{mpk}, i, r, \text{sk}_{i,r}}(\text{ct}_R) = \mu \right] = 1.$$

The scheme is $1$-key secure for random challenge against uniform adversaries (or secure for the purpose of this work) if

$$\{ (1^\lambda, 1^N, \text{mpk}, R, i^*, \mu_0, \text{sk}_{i^*, -R[i^*]}, \text{ct}_0) \}_{\lambda \in \mathbb{N}} \approx \{ (1^\lambda, 1^N, \text{mpk}, R, i^*, \mu_0, \text{sk}_{i^*, -R[i^*]}, \text{ct}_1) \}_{\lambda \in \mathbb{N}}$$

with the components being

$$\{ (\text{mpk}, \{\text{sk}_{j,s} \}_{j \in [N], s \in \{0,1\}}) \xleftarrow{} \text{Gen}(1^\lambda, 1^N) ; R \xleftarrow{} \{0,1\}^N ; i^* \xleftarrow{} [N] ; \mu_b \xleftarrow{} \{0,1\}^\lambda ; \text{ct}_b \xleftarrow{} \text{Enc}(1^\lambda, \text{mpk}, R, \mu_b) \}$$

for all polynomially bounded $N = N(\lambda)$, where the computational indistinguishability only has to hold against uniform adversaries.

---

17. The lower bound thus also applies to all mildly expressive attribute-based encryption schemes.
18. $N$ needs not be a computable function of $\lambda$. This does not make the security definition "non-uniformly", as a standard guessing argument (with advantage sign correction) applies to an interactive formulation in which the uniform and efficient $\mathcal{A}$ chooses $N$. 
Theorem 14 (\[\text{Theorem 2}\]). For all secure restricted BE,

\[
\max |ct| \cdot \max T_{\text{Dec}} \geq \frac{N}{1000}
\]

for all polynomially bounded \(N = N(\lambda)\) and sufficiently large \(\lambda\), where \(ct\) runs through all possible ciphertexts and \(T_{\text{Dec}}\) the time to probe \(R\) and produce output by \(\text{Dec}\), both for \(R\) of length \(N\).

We remark that “for sufficiently large \(\lambda\)” is necessary because asymptotic security, by definition, is a tail property unaffected by finitely many \(\lambda\)’s. The bound starts to hold once the scheme starts to be secure against the adversary used in the proof. While the statement and the proof here apply to perfectly correct schemes with polynomial security, it is straight-forward to adapt them for schemes with sufficient (say, constant) gap between correctness and security.

To prove Theorem 14, we need the following lemma:

Lemma 15 (adapted from [Unr07; Theorem 2]). For all \(N, P \in \mathbb{N}\) subject to \(1 \leq P \leq N\), distribution \(D\) supported over a finite set \(Z\), function \(F : Z \times \{0,1\}^N \rightarrow \{0,1\}^S\), there exists a function \(G : Z \times \{0,1\}^N \rightarrow \{0,1,\perp\}^N\) such that

\[
|\{j \in [N] : G(z,R)[j] \neq \perp\}| \leq P \quad \text{for all } z \in Z \text{ and } R \in \{0,1\}^N
\]

and for all\(^{19}\) oracle (randomized) algorithm \(B^Y\) making at most \(T\) queries to \(Y\),

\[
|\Pr [B^R(z, F(z,R)) \rightarrow 1] - \Pr [B^H(z,F(z,R)) \rightarrow 1]| \leq \sqrt{\frac{ST}{2P}},
\]

where

\[
R \overset{\delta}{\leftarrow} \{0,1\}^N, \quad z \overset{\delta}{\leftarrow} D, \quad H[j] \begin{cases} = G(z,R)[j], & \text{if } G(z,R)[j] \neq \perp; \\ \overset{\delta}{\leftarrow} \{0,1\}, & \text{if } G(z,R)[j] = \perp.
\end{cases}
\]

Proof (Theorem 14). Define

\[
S = 1 + \max |ct|, \quad T = 1 + \max \{\text{number of bits in } R \text{ probed by } \text{Dec}\}.
\]

For \(\lambda, N \geq 1\), it is necessary that \(|ct| \geq 1\) because \(ct\) can encode any string \(\mu\) of length \(\lambda\), and that \(\max T_{\text{Dec}} \geq T\) because \(\text{Dec}\) performs all the probes and, in addition, produces at least 1 bit of output. Therefore,

\[
\max |ct| \cdot \max T_{\text{Dec}} \geq \frac{\max |ct| + 1}{2} \cdot \max T_{\text{Dec}} \geq \frac{ST}{2}.
\]

It remains to prove \(ST \geq \frac{2N}{1000}\) for sufficiently large \(\lambda\). It suffices to consider the case when \(N \geq 2\) and \(ST \leq 2N\).

We prepare for Lemma 15. Let \(P\) be determined later, and

\[
z = \left( \mu, z_{\text{Enc}}, \text{mpk}, \langle sk_{j,s} \rangle_{j \in [N], s \in \{0,1\}} \right) \overset{\delta}{\sim} D = \left\{ z_{\text{Enc}} : \text{randomness for } \text{Enc} \left( \text{mpk}, \langle sk_{j,s} \rangle_{j \in [N], s \in \{0,1\}} \right) \overset{\delta}{\sim} \text{Gen}(1^N) \right\},
\]

\[
F(z,R) = 0^{S-|ct|-1} \parallel |ct| \quad \text{where } ct \leftarrow \text{Enc}(\text{mpk}, R, \mu; z_{\text{Enc}}).
\]

Let \(G\) be the function guaranteed by Lemma 15 and make \(B^Y(z,f)\) do the following:

\(^{19}\)Here, \(B^Y\) need not be efficient for the lemma to hold. The particular \(B^Y\) used in this work is efficient.
• Sample \(i^* \in \{N\}\) and query \(r^* \leftarrow Y[i^*]\).
• Read \(\mu, \text{mpk, sk}_i, \ldots\) from \(z\). Read \(ct\) from \(f\).
• Run \(\mu' \in \text{Dec}^{\mu, z, f, \text{sk}_i, \ldots, Y, ct}()\).
• Output 1 if and only if \(\mu = \mu'\).

Note that \(B\) indeed makes at most \(T\) queries to \(Y\), the first to obtain \(r^*\) and the rest to run \(\text{Dec}\).

For \(w \in \{1, 2, 3, 4, 5\}\), write \(p_w\) for \(\Pr[B^{Y^w}(z, f; i^*) \rightarrow 1]\), where

\[
i^* \in \{N\}, \quad Y_1 = R, \quad Y_2[j] = \begin{cases} G(z, F(z, R))[j], & \text{if } G(z, F(z, R))[j] \neq \bot; \\ \{0, 1\}, & \text{if } G(z, F(z, R))[j] = \bot; \end{cases} \quad Y_3[j] = \begin{cases} G(z, F(z, R))[j], & \text{if } j \neq i^* \text{ and } G(z, F(z, R))[j] \neq \bot; \\ \{0, 1\}, & \text{if } j = i^*; \end{cases} \quad Y_4[j] = \begin{cases} R[j], & \text{if } j \neq i^*; \\ \{0, 1\}, & \text{if } j = i^*; \end{cases} \quad Y_5[j] = \begin{cases} R[j], & \text{if } j \neq i^*; \\ \{0, 1\}, & \text{if } j = i^*. \end{cases}
\]

By the correctness of the restricted BE scheme, \(p_1 = 1\).

From Lemma 15,

\[
|p_1 - p_2| \leq \sqrt{\frac{ST}{2P}}, \quad |p_4 - p_3| \leq \sqrt{\frac{ST}{2P}}.
\]

Here, the second inequality is obtained by applying the lemma to

\[
Y^w = B^{Y^w}(z, f; i^*), \quad Y[j] = \begin{cases} Y[j], & \text{if } j \neq i^*; \\ \{0, 1\}, & \text{if } j = i^*. \end{cases}
\]

Clearly, \(|p_2 - p_3| \leq \frac{P}{N}\). Setting \(P = \left\lceil \frac{3 \sqrt{STN^2}}{2} \right\rceil\), we have

\[
|p_1 - p_4| \leq |p_1 - p_2| + |p_2 - p_3| + |p_3 - p_4| \leq \sqrt{\frac{ST}{2P}} + \frac{P}{N} + \sqrt{\frac{ST}{2P}} \leq \sqrt{\frac{ST}{2N}} + \frac{1}{N} < 4 \sqrt{\frac{ST}{2N}},
\]

where the last inequality follows from \(N \geq 2\). By how \(Y[i^*]\) is set,

\[
p_4 = \frac{p_1 + p_5}{2} \quad \Rightarrow \quad p_5 = p_1 - 2(p_1 - p_4) \geq p_1 - 2|p_1 - p_4| > 1 - 8 \sqrt{\frac{ST}{2N}}.
\]

Consider the following adversary \(A(\text{mpk, R, i^*, } \mu_0, \text{sk}_i, \ldots, \neg R[i^*], ct)\) against the security of the restricted BE scheme:

• Construct \(Y_5\) from \(R\) and let \(r^* \leftarrow Y_5[i^*] = \neg R[i^*]\).
• Run \(\mu' \in \text{Dec}^{\mu, z, f, \text{sk}_i, \ldots, Y_5, ct}()\), i.e., pretend \(R[i^*]\) were \(\neg R[i^*]\) and try decrypting using the (supposedly non-decrypting) key given to \(A\).
• Output 1 if and only if \(\mu' = \mu_0\).
If $ct = ct_1$ is an encryption of $\mu_1$, then $\mu_0$ is uniformly random and independent of everything else, hence

$$\Pr[\mathcal{A}(\cdots) \rightarrow 1 \text{ with } ct = ct_1] \leq 2^{-\lambda}.$$ 

Note that $\mathcal{A}$ is a uniform adversary. By the security of the restricted BE scheme,

$$p_5 = \Pr[\mathcal{B}^{Y_5}(z, f; i^*) \rightarrow 1] = \Pr[\mathcal{A}(\cdots) \rightarrow 1 \text{ with } ct = ct_0] \leq 2^{-\lambda} + \operatorname{negl}(\lambda) < \frac{1}{5}$$

for sufficiently large $\lambda$, which gives

$$1 - 8\sqrt{\frac{ST}{2N}} < \frac{1}{5} \implies ST > \frac{2N}{1000} \quad \square$$

**Corollary 16 (\|).** For all secure AH-BTR,

$$\max |ct| \cdot \max T_{\text{Dec}} \geq \frac{N}{1000}$$

for all polynomially bounded $N = N(\lambda)$ and sufficiently large $\lambda$,\(^{20}\) where $T_{\text{Dec}}$ only counts the time to probe $pk_j$'s and produce output. Ignoring $\operatorname{poly}(\lambda)$ factors, Construction 3 achieves all possible optimal trade-offs in terms of the exponents over $N$ in the dependency of ciphertext size and (actual) decryption time, fully demonstrating the Pareto front of AH-BTR efficiency.

**Proof (Corollary 16).** Suppose $(\text{ahBTR.Gen, ahBTR.Enc, ahBTR.Dec, ahBTR.Trace})$ is a secure AH-BTR and construct the following restricted BE scheme:

- $\text{Gen}(1^N)$ runs
  $$(pk_j, s, sk_j, s) \xleftarrow{\$} \text{ahBTR.Gen}() \text{ for } j \in [N], s \in \{0, 1\}$$
  and outputs $mpk = \{pk_j, s\}_{j \in [N], s \in \{0, 1\}}$ with $\{sk_j, s\}_{j \in [N], s \in \{0, 1\}}$.

- $\text{Enc}(mpk, R, \mu)$ runs and outputs
  $$ct \xleftarrow{\$} \text{ahBTR.Enc}(\{pk_j, R[j]\}_{j \in [N]}, \mu).$$

- $\text{Dec}^{mpk, i, r, sk_i, r, ct()}$ runs $\text{ahBTR.Dec}^{K, ct}(N, i, sk_i, r)$, where $K$ is an oracle implemented by $\text{Dec}$ for $\text{ahBTR.Dec}$ to probe $pk_j$'s. Whenever $\text{ahBTR.Dec}$ probes $pk_j[m_0]$, we make $\text{Dec}$ probe $R[j]$ and answer $pk_j, R[j][m_0]$.

It is straightforward to verify that the constructed scheme is correct and secure. Since a restricted BE ciphertext is precisely an AH-BTR ciphertext, each probe to $pk_j$'s by $\text{ahBTR.Dec}$ translates to exactly one probe to $R[j]$ by $\text{Dec}$ with no more additional probes by $\text{Dec}$ on its own, and $\text{Dec}$ outputs whatever $\text{ahBTR.Dec}$ outputs, the corollary follows from Theorem 14. \(\square\)
